APPENDIX G

CROSS-REFERENCE BETWEEN YMP LICENSE APPLICATION FEPS AND SITE RECOMMENDATION FEPS

G1. INTRODUCTION

The iterative process for FEP analysis was initiated to support TSPA-SR and continued through the TSPA-LA. For TSPA-SR, an initial list of FEPs relevant to Yucca Mountain was developed from a comprehensive list of FEPs from radioactive waste disposal programs in other countries (Freeze et al. 2001 [DIRS 154365], Section 2.1) and was supplemented with additional YMP-specific FEPs from YMP literature, technical workshops, and reviews (Freeze et al. 2001 [DIRS 154365], Sections 2.2 to 2.4).

The all-inclusive TSPA-SR FEP identification approach produced 1,656 specific FEPs and 152 associated classifications (derived from Version 1.0 of the NEA International FEP Database (SAM 1997 [DIRS 139333]) and from YMP-specific information), and resulted in considerable redundancy in the FEPs list because the same FEPs were frequently identified by multiple sources. To eliminate the redundancy and to create a more efficient aggregation of FEPs to carry forward into the TSPA-SR screening process, each of the 1,808 FEP entries was subjected to a classification process (Freeze et al. 2001 [DIRS 154365], Section 3.2). After further refinement, this classification process produced a list of 328 primary FEPs. Each of these primary FEPs encompassed a single process or event or a few closely related or coupled processes or events that could be addressed by a specific screening decision (BSC 2005 [DIRS 173800], Section 3).

The NRC and other agencies reviewed the list of FEPs and presented a number of recommendations for improvement. One specific recommendation was to eliminate all FEPs with multiple (that is, included and excluded) screening decisions. Another enhancement was to eliminate the secondary FEPs after ensuring that the concepts represented by them were included in FEPs on the TSPA-LA FEP list.

The cross-reference tables (Tables G-1 and G-2) present the relationship between the TSPA-LA FEPs and the TSPA-SR FEPs (primary and secondary). The cross-referencing from TSPA-LA FEPs to TSPA-SR FEPs (Table G-1) shows that the TSPA-LA FEP addressed issues contained within the TSPA-SR FEP(s). The cross-referencing from TSPA-SR FEPs to TSPA-LA FEPs (Table G-2) indicates that the aggregate of all TSPA-LA FEPs tied to that specific TSPA-SR FEP addresses all the major issues raised by the TSPA-SR FEP.

These tables are provided to assist in demonstrating that the TSPA-LA FEP list is complete and comprehensive.

APPENDIX H

DESCRIPTION OF FEPS DATABASE

DESCRIPTION OF FEPS DATABASE

The 19 tables that comprise the FEPs database and the fields contained therein are described below.

Columns: This table contains the name of the columns for the FEPs matrix form.

- Counter: Primary key to keep the columns in the desired order.
- Column Number: Column number as specified in the Matrix_Column field of the FEPS Table or MatrixSecondaries Table. They are not necessarily ordered or sequential.
- Column: Name of the column to be displayed on the FEPs matrix.
- ColumnAbbr: Abbreviation of the column name for the printed report.

DeletedFEPInfo: This table contains a list of those TSPA-SR FEPs that were deleted for TSPA-LA. No scope was actually eliminated unless there was a specific design change that caused the elimination of the FEP; however, combining and splitting of FEPs caused some FEPs to be deleted.

- YMP FEP Database Number: The number of the deleted FEP.
- Notes: Information about why the FEP was deleted.

DIRS_Descriptions: This table contains the DIRS descriptions that are used to produce the lists of direct and indirect inputs in the analysis report and the detail report. These descriptions include author, year of publication, and title.

- DIRS_No: The 6 character DIRS number.
- Description: A Memo field that contains the DIRS descriptions for the reference.
- Code: This is a single digit code (1, 2, 3, or 4) that assigns the reference to one of the four areas of the list of inputs and references (documents = 1; codes and standards = 2; input data = 3; and software = 4).
- Title: This field contains the DIRS description shortened to citation style (e.g., author, year, title).

FEP History File: This table contains the changes made to the FEPs database from the preliminary TSPA-LA FEP list (DTN: MO0301SEPFEPS1.000 [DIRS 161496]) through the final qualified TSPA-LA FEP data set (Technical Output DTN: MO0706SPAFEPLA.001). Whenever a change is made to any field in the FEPS Table, the pre-change information in all of the fields of the FEPS table (even unchanged fields) is automatically copied verbatim to the corresponding fields of the FEP History File (listed below). Descriptive information about each change must be entered manually in the Notes field (the update routine will not allow the changes to be saved until something is entered in the Notes field). The FEP History File can,

therefore, be used to examine all changes made to the FEP information in the FEPS table. For example, if the Notes field indicates, "Description edited," then the existing YMP Description in the FEP table can be compared to the previous YMP Description in the FEP History File to see the differences.

- YMP FEP Database Number: The FEP number.
- FEP Name: The FEP name prior to the modification.
- Source Identifier: The source identifier of the FEP prior to the modification.
- YMP Description: The FEP description prior to the modification.
- Screening Decision: The screening decision of the FEP prior to the modification.
- Screening Justification: (Previously called Screening Argument.) The screening justification of the FEP prior to the modification. Screening justifications are only used for excluded FEPs; if the FEP was excluded prior to the modification, there would be an entry in this field regardless of the screening decision after the modification.
- TSPA Disposition: The TSPA disposition of the FEP prior to the modification. TSPA dispositions are only used for included FEPs; if the FEP was included prior to the modification, there would be an entry in this field regardless of the screening decision after the modification.
- Supplemental Discussion: The supplemental discussion related to the FEP prior to the modification.
- AMR: The input FEP AMR prior to the modification. With the publication of this analysis report, there are no more input FEP AMRs. However, the categorization is still useful for viewing and reviewing FEPs, therefore, the field was retained.
- Barrier: This is the barrier to which the FEP is assigned based upon its primary row in the FEP Matrix prior to modification.
- Modified By: The last person to modify the FEP prior to this modification.
- Mod Date: The date the FEP was last modified prior to this modification.
- Mod Time: The time the FEP was last modified prior to this modification.
- Notes: Descriptive information about this modification. This information is also prepended to the Notes (Historical Notes) field of the FEPs table.
- Matrix_Row: The matrix row of the FEP prior to the modification.
- Matrix_Column: The matrix column of the FEP prior to the modification.

- EntryDate: The date this modification was accomplished.

- Keyword History: The former descriptor phrases associated with the FEP. Descriptor phrases were developed during interim screening to capture finer conceptual or modeling details, generally associated with the source FEPs that were not explicitly identified in the FEP name or description. Descriptor phrases were eliminated in May of 2004 but the field was maintained because of the descriptor phrases in the FEP table prior to that date. Descriptor phrases were a predecessor to the TSPA-LA keywords.

FEPMappingNEAtoLA: This table contains the source FEP (NEA and YMP-specific) identifiers and the corresponding TSPA-LA FEP numbers that address the source FEPs. Source FEPs are listed in the SourceFEPs table and source FEP identifiers are listed in Table F-1.

- Unique No: Source FEP number/identifier.

- LA FEP Number: TSPA-LA FEP number.

FEPMappingSRtoLA: This table contains the TSPA-SR FEP numbers and the related TSPA-LA FEP numbers.

- SR FEP Number: TSPA-SR FEP number.

- LA FEP Number: TSPA-LA FEP number.

FEPS: This is the main TSPA-LA FEP table and contains most of the data describing a specific FEP.

- YMP FEP Database Number: Primary key used for identifying the FEP within the database. The number was derived from the TSPA-SR FEP number. In general, the last numeric character of the TSPA-SR number was replaced with an alpha character for the TSPA-LA.

- FEP Name: Short, descriptive title for the FEP.

- Source Identifier: This field once contained the link to the source FEP number/identifier. However, this field is not used for TSPA-LA and is maintained merely to preserve the historical traceability of the FEP.

- YMP Description: Description of each FEP and its potential relevance to YMP.

- Screening Decision: A statement of whether the FEP is included in the quantitative TSPA-LA models or excluded from TSPA-LA on specific criteria (viz. Low Probability, Low Consequence, and/or By Regulation).

- Screening Justification: (Formerly labeled Screening Argument) A summary discussion of the technical basis for exclusion, with citations to appropriate TSPA-LA AMRs and other documents (for excluded FEPs, this is the key text).

- TSPA Disposition: A summary discussion of the implementation of the FEP in TSPA-LA, with citations to appropriate supporting technical AMRs (for included FEPs, this is the key text).

- AMR: Identifies the input FEP AMR. With the publication of this analysis report, there are no more input FEP AMRs. This field was retained because it provides a convenient way to categorize FEPs for viewing and reviewing.

- Barrier: This is the barrier to which the FEP is assigned based upon its primary row in the FEP Matrix.

- Modified By: Name of the last person to modify the FEP record and the computer on which the modification was made.

- Mod Date: Date the FEP record was last modified.

- Mod Time: Time the FEP record was last modified.

- Historical Notes: The entire history of miscellaneous notes and comments related to a FEP. All changes made subsequent to the preliminary TSPA-LA FEP list (DTN: MO0301SEPFEPS1.000 [DIRS 161496]) are automatically captured in the FEP History File Table and the associated Notes are prepended to this field separated from previous notes by a line of asterisks. Prior to the development of data set DTN: MO0501SEPFEPLA.001 [DIRS 172601], the name of this field was "Notes".

- Matrix_Row: Row number of the FEP's home row on the matrix (see Rows Table for row names corresponding to row numbers).

- Matrix_Column: Column number of the FEP's home row on the matrix (see Columns Table for column names corresponding to column numbers).

- Included: A placeholder for the included/excluded status of the FEP. It is completed each time the FEPs database program is initiated. If the Screening Decision is "Included", the word "Included" is written in this field. If the screening decision contains the word "Excluded" regardless of the reason, the word "Excluded" is written in this field. A FEP cannot be both included and excluded. This column with the single word in it makes the coding to do the transform query for building the matrices easier.

- Notes: This field was added during the development of data set DTN: MO0501SEPFEPLA.001 [DIRS 172601], and is different from the "Historical Notes" field. It provides additional information, as appropriate, regarding the traceability of FEPs and the suite of analyses reports.

FEPS_REV00_ICN02: This is the TSPA-SR FEPs table (BSC 2002 [DIRS 159684]) in its entirety. The table is retained for historical purposes. A mapping of these TSPA-SR FEPs to the appropriate TSPA-LA FEPs is provided in FEPMappingSRtoLA Table.

- YMP FEP Database Number: Numeric identifier that places the FEP in the proper location within the database structure. The numbering scheme follows a hierarchical structure classifying FEPs into layers (x…), categories (x.x…), headings (x.x.xx…), primary FEPs (x.x.xx.xx…), and secondary FEPs (x.x.xx.xx.xx).

- FEP Name: Short, descriptive title of the FEP.

- FEP Class: Identification of primary, secondary, and classification (layer, category, heading) entries. Primary FEPs are those FEPs for which the YMP has developed and documented screening discussions. Secondary FEPs are mapped to primary FEPs either because they are redundant with the associated primary FEP or because they represent a subcase of the primary FEP that is more effectively addressed at a higher level. Secondary FEPs are retained in the database for completeness, but users of the database are referred to the related Primary FEPs for the screening discussions.

- NEA Category: Alphanumeric identifier used for the preliminary mapping of the FEPs relative to the NEA database headings. This field is based on preliminary mapping and has been superseded by the YMP FEP Database Number field. It is retained only for traceability to earlier versions of the database. Note that for new FEPs that were identified during and subsequent to the December 1998 to April 1999 workshops, the Source Identifier is repeated in this field.

- Related Primary FEP(s): Identification of entries containing related information. For primary FEPs, other related primary FEPs (if any) are listed. For secondary FEPs and classification entries, this field is blank. Related secondary and classification FEPs can instead be determined through the hierarchical numbering scheme.

- Source Identifier: Alphanumeric identifier that provides traceability to the originator (e.g., NEA contributing program, YMP-specific workshop, AMR, etc.). Source identifier information is in Table F-1. Note that the Source Identifier is not related to the NEA Category or YMP FEP Database Number.

- YMP Primary Description: Description of each primary FEP and its potential relevance to YMP, typically edited from the Originator FEP Description. Where secondary FEPs are associated with a primary FEP, the description also includes all of the features, events and processes described by the secondary FEPs. For shared FEPs, descriptions from each input FEP AMR are listed but are not integrated.

- Originator Description: Verbatim text of the FEP description from originator documentation. The originator is noted in parentheses where possible.

- Screening Decision: A statement of whether the FEP was included in the quantitative TSPA-SR models or excluded from the TSPA-SR on specific criteria provided by the regulations.

- Screening Argument: A summary discussion of the technical basis for the TSPA-SR Screening Decision, with citations to appropriate AMRs (for excluded FEPs, this is the key text).

- TSPA Disposition: A summary discussion of the treatment of the FEP in the TSPA-SR, with citations and cross-references to the appropriate AMRs (for included FEPs, this is the key text).

- Supplemental Discussion: Provides additional information supporting the TSPA-SR Screening Decision beyond what is summarized in the Screening Argument and TSPA Disposition fields.

- AMR: Identifies the TSPA-SR FEP AMR where the screening discussion was documented. Verbatim text for several fields including the Screening Decision, Screening Argument, TSPA Disposition, Supplemental Discussion, and Treatment of Secondary FEPs was taken from the input FEP AMR. The input FEP AMR identifier also indicates the technical subject area in which the FEP was grouped. For shared FEPs, all of the input AMRs are listed.

- IRSR: Identifies NRC IRSR subissues related to the FEP.

- Modified By: Name of the last person to modify the FEP record.

- Mod_Date: Date of last modification to the FEP record.

- Mod_Time: Time of last modification to the FEP record.

- Notes: Miscellaneous notes and comments related to the FEP.

- F Keyword: Placeholder for an identifier feature keyword from a specified list that is used for keyword searches. This field was never implemented for TSPA-SR and is blank.

- E Keyword: Placeholder for an identifier event keyword from a specified list that is used for keyword searches. This field was never implemented for TSPA-SR and is blank.

- P Keyword: Placeholder for an identifier process keyword from a specified list that is used for keyword searches. This field was never implemented for TSPA-SR and is blank.

- Treatment of Secondary FEP(s): For primary FEPs, a list of the underlying secondary FEPs is provided with a short description of the relationship of each secondary FEP to the primary FEP and a summary of how the secondary FEP is addressed in the Screening Argument or TSPA Disposition.

FEPtoRef: This table relates references to individual FEPs. Unlike the Inputs Table it merely ties the DIRS number to the FEP number.

- FEP_No: FEP number.
- DIRS_No: DIRS number of the reference associated with this FEP.

Inputs: This table is a replica of the check copy DIRS database identified by FEP.

- FEP_No: FEP number for the input.
- DIRS_No: DIRS number of the reference. (This input is linked to the DIRS_Descriptions Table to obtain the rest of the citation.)
- Source: Where in the reference the information comes from.
- Input Description: How the information is used in the FEP.
- In_Dir: Indirect or Direct Input?
- Input_Category: Type of input.
- Q Status: Qualified or Not Qualified?
- TBV_TBD_Status: TBV/TBD status from the DIRS database.

KeywordsSource: This table contains a list of TSPA-LA keywords and the associated TSPA-LA FEP. Keywords capture the key aspects of the FEP name, FEP description, and relevant source FEPs. The set of keywords for a single FEP represents the basic scope of the FEP (as defined in the FEP name and FEP description) as well as any finer conceptual or modeling details identified only in relevant source FEPs. TSPA-LA keywords derived from descriptor phrases (see the "FEP History File" Table). They were created by parsing the individual descriptor phrases into individual keywords.

- Keyword: Keywords used for the keyword search function.
- FEP No: Associated TSPA-LA FEP.

MatrixSecondaries: This table contains the matrix rows and columns that a FEP is related to in addition to the home matrix rows and columns identified in the FEPS Table. It is appended to the FEP table to build the FEP matrix. There is no limit to the number of additional matrix boxes that a FEP can relate to.

- YMP FEP Database Number: The TSPA-LA FEP number.
- FEP Name: The name of the FEP.

- Matrix_Row: A secondary matrix row that the FEP "resides" in. (Note: a FEP can reside in multiple secondary matrix rows as appropriate.)

- Matrix_Column: A secondary matrix column that the FEP "resides" in. (Note: a FEP can reside in multiple secondary matrix columns as appropriate.)

- Included: This field is a placeholder that is updated each time the FEP Database is opened. It contains either the word "Included" or "Excluded". Its only purpose is to facilitate the query that fills the grid squares.

Potential FEP Log: This table contains information about the tracking and resolution of all potential FEPs identified between the preliminary TSPA-LA FEP list (DTN: MO0301SEPFEPS1.000 [DIRS 161496]) and the final TSPA-LA FEP data set.

- Log #: A key to track the order of FEP configuration management entries.

- Date Submitted: The date the potential FEP was entered into FEP configuration management.

- Submitted By: The name of the person (or organization) who entered the potential FEP into configuration management.

- Issue Title: A short title/description of the potential FEP.

- Source: The name of the person (or organization) that identified the potential FEP issue. Where appropriate, a source document or e-mail may be identified.

- Discussion of Issue: A discussion of the potential FEP and the reason it might be considered in TSPA-LA.

- Resolution: How the potential FEP was dispositioned (i.e., new FEP, change to existing FEP, or no change).

- Date of Resolution: The date the final disposition of the potential FEP was accomplished.

- Supplemental Information: Additional information to support the resolution of the issue.

Rev Data: This table stores the revision identifier of the data file (e.g., DTN) and of the AMR. The data file revision information is displayed throughout the FEPs database to allow users to ensure that they are using the version of the data that is desired. (Note: There is no software requirement to use the most up-to-date data.) The analysis report revision information is printed in the footer of the analysis report.

- RevNumber: The data file identifier of this revision of the data file. Normally the DTN is included in this field.

- RevDate: The date of the data file revision.

- AMR_Rev: The revision number of the analysis report.
- AMR_Date: The date of the AMR revision (month and year).

RIT_Status: This table contains the include/exclude status of each FEP as of August 2005. It is maintained to produce a status report showing changes to the data since that date.

- YMP FEP Database Number: The FEP number.
- Included: Status, included or excluded.

Rows: This table contains the name of the rows for the FEPs matrix form:

- Counter: Primary key to keep the rows in the desired order.
- Row Number: Row number as specified in the Matrix_Row field of the FEPS Table or MatrixSecondaries Table. They are not necessarily ordered or sequential.
- Row: Name of the row to be displayed on the FEPs matrix.
- RowAbbr: Abbreviation of the row name for the printed report.

Source FEP Categories: This table contains the identifiers for the specific categories of source (NEA and YMP-specific) FEPs. These specific categories are listed in Table F-1.

- SourceCode: Abbreviation used in the source identifier category.
- SourceCategory: The name of the source identifier category.

SourceFEPs: This table contains a list of source FEPs and their descriptions. Source FEPs are NEA and YMP-specific FEPs that provide the basis for the TSPA-LA FEP list. NEA source FEPs and descriptions are taken directly from Version 1.1 of the NEA International FEP database (OECD 2000 [DIRS 152952], Appendix D). Applicable (Section F1) source FEPs are explicitly mapped to one or more TSPA-LA FEPs (see Table "FEPMappingNEAtoLA" or Appendix F) that capture (sometimes explicitly and sometimes implicitly) the subject of the source FEP. In some cases, the source FEPs identify finer conceptual or modeling details that are not otherwise identified explicitly (although they are captured implicitly) in the FEP name and/or FEP description. A list of source FEP categories can be found in Table F-1.

- FEP name: The name of the source FEP.
- FEP description: The description of the source FEP, verbatim from the source.
- Unique No: The source FEP number/identifier assigned to the source FEP.
- Class Code: Numeric identifier for the source identifier category used to group source FEPs in database pull-down menus (corresponds to different source identifiers in Table F-1).

SRFEPTree: This table defines the hierarchical structure of the TSPA-SR FEPs. This table is used to build the TSPA-SR FEPs Tree.

- YMP FEP Database Number: The TSPA-SR FEP number.
- FEP Name: The name of the TSPA-SR FEP.
- ParentFEP: The FEP one level above this FEP.
- Description: The FEP description.

APPENDIX I

ANALYSIS OF SENSITIVITY OF TRANSPORT TO CHANGES IN FRACTURE APERTURE

This appendix is referenced in FEPs 1.2.10.01.0A (Hydrologic Response to Seismic Activity); 2.2.01.05.0A (Radionuclide Transport in the Excavation Disturbed Zone); 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults); 2.2.06.02.0B (Seismic Activity Changes Porosity and Permeability of Fractures); 2.2.10.05.0A (Thermo-Mechanical Stresses Alter Characteristics of Rocks above and below the Repository); 2.2.10.14.0A (Mineralogic Dehydration Reactions); and 2.2.12.00.0A (Undetected Features in the UZ).

I1. INTRODUCTION

This appendix evaluates the potential for changes to the hydrogeologic system caused by fault displacement to affect radionuclide transport in the unsaturated zone at Yucca Mountain. The repository is bounded on the west by the Solitario Canyon fault and on the east by the Bow Ridge Fault. The northern boundary of this structural block is bounded by the Drill Hole Wash Fault. Intrablock faults include the Ghost Dance, Sundance, and Dune Wash Faults (BSC 2004 [DIRS 169855], Figure C3-1). For the purposes of this analysis, the focus is on two possible effects of fault displacement along the bounding faults: (1) uniform change in fracture properties throughout the UZ flow model domain and (2) change in fracture properties within the faults only. These two hypothetical end-member cases model the bounding cases of mechanical strain being either uniformly distributed throughout the strata bounded by the faults or localized to the individual fault zones. In the physical system, the strain would be spatially distributed in some manner that lies between these end-member cases. This evaluation used the bounding case estimates to determine whether FEPs 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults) and 2.2.06.02.0B (Seismic Activity Changes Porosity and Permeability of Fractures) can be excluded.

These two end-member cases were evaluated by simulating the flow and transport in the unsaturated zone for a pulse input tracer at the repository location. For a specific cross-section, computer simulations were performed assuming (1) a change in fracture properties throughout the UZ models (which assumes all fracture apertures are uniformly altered), and (2) a change in fracture properties in the fault zones only. Simulations were performed for the present-day climate and a wetter, glacial-transition climate case. These climates were chosen to span a representative range of climates for future conditions at Yucca Mountain (Section I2.1.4). Tracer breakthrough curves computed at the water table were used to examine the potential impact induced on transport in the unsaturated zone.

The approach for the analysis of fault displacement effects on transport in the unsaturated zone is divided into two distinct components: (1) a review of site description information which provides a basis for defining bounding conditions and for understanding the physical significance of the results (Section I2); and (2) a modeling component to provide quantitative analysis of the sensitivity of the unsaturated zone flow system to changes in hydrologic parameters (Section I3).

I2. SENSITIVITY ANALYSES

I2.1 SITE DESCRIPTION INFORMATION

The spatial and temporal patterns of faulting and fracturing of the volcanic bedrock are the fundamental elements of the structural geology of the repository for high-level radioactive

wastes at Yucca Mountain. To document and discuss these patterns, a comprehensive program of geologic mapping and fractured rock mass studies has been conducted as an integral part of the site characterization. Of particular importance to this analysis are geologic observations related to displacement in fault zones and observations of the characteristics of the fault zones made during the excavation of the ESF and in the ECRB Cross Drift. The observations are briefly described in Section I2.1.1. These observations provide a basis for determining the reasonableness and appropriateness of the range of inputs used in the modeling analysis in Section I3 and for interpreting the level of conservatism represented by the models.

However, the primary controlling factor for amount of flux through the unsaturated zone is the amount of precipitation available to infiltrate and percolate through the unsaturated zone. This variable is highly dependent on climate conditions. To address this variable, present-day average and glacial-transition climate conditions (BSC 2004 [DIRS 170002], Table 6-1) were used as a representative range of climate conditions. The differences in these climate states are briefly explained in Section I2.1.4.

I2.1.1 Geologic Setting

The Yucca Mountain area is cut by steeply dipping, north-south-striking normal faults which separate the Tertiary volcanics into blocks one to four kilometers wide (Scott 1990 [DIRS 106751]). The repository lies in the central block of the central Yucca Mountain structural domain. The central block is bounded on the west by the Solitario Canyon Fault, on the east by the Bow Ridge Fault, and on the north by the northwest-striking Drill Hole Wash Fault. The Bow Ridge and Solitario Canyon Faults dip steeply toward the west, and displacement, amount of brecciation, and number of associated splays varies considerably along their trace (Scott and Bonk 1984 [DIRS 104181]; Day et al. 1998 [DIRS 101557]). The southern boundary is marked by a transition to structural styles that accompany greater magnitudes of extension and continue south. Intrablock faults include the Ghost Dance, Sundance, and Dune Wash Faults.

Surface geologic mapping (Scott and Bonk 1984 [DIRS 104181]; Day et al. 1998 [DIRS 101557]), underground mapping of the ESF, geophysical surveys, and borehole studies show that the Yucca Crest subblock is little deformed, and cut only by widely spaced intrablock faults (Ghost Dance and Dune Wash). Within structural blocks, small amounts of strain are accommodated along intrablock faults. In many cases, intrablock faults appear to represent local structural adjustments in response to displacements on the block-bounding faults. Many of the intrablock faults within this part of Yucca Mountain are short, discontinuous, have minor cumulative displacement (1 to 10 m), and represent the localization of slip along pervasive preexisting weaknesses in the rock mass (Potter et al. 1996 [DIRS 106582]; 1996 [DIRS 106583]). In some cases, intrablock faults are expressions of hanging wall or footwall deformation that affect the block within a few hundred meters of the block-bounding faults. The eastern and southern edges of the central block, however, are cut by numerous faults associated with block margin deformation (Solitario Canyon and Bow Ridge Faults).

I2.1.2 Significance of Geologic Setting to the Analysis

The description in Section I2.1.1 suggests that an analysis of fault displacement effects needs to be considered from two perspectives: the impact on fractures throughout the repository as a whole, and the effect on fractures in the immediate vicinity of the faults only. Furthermore, the range of fault characteristics that was described supports the idea that movement on the Solitario Canyon Fault may be considered the bounding scenario.

The fracture network at Yucca Mountain acts as a significant preexisting weakness in the rock mass that can accommodate extensional strain through distributed slip along many reactivated joints. Evidence for reactivation of joints includes the presence of thin breccia zones along cooling joints and observable slip lineations along joint surfaces (Sweetkind et al. 1996 [DIRS 106957]). There are a number of primary limitations to fracture characteristics within the Paintbrush Group that are related to stratigraphy, upon which any later tectonic signature (such as fault displacement) is superimposed. The existence of distributed slip suggests that changes in strain (such as would be associated with a significant fault displacement) are likely to be propagated throughout the repository area. Also, some fault zones (such as the Ghost Dance and Solitario Canyon) may be on the order of 100 to 400 m wide. Although strain is expected to diminish with distance from the fault, these observations suggest that the effect of strain distributed in the fractures throughout the repository should be considered (Section I3.3.2).

The presence of gouge and brecciated zones only in limited proximity to the fault planes, however, suggests that much of the strain will be mechanically dissipated within or near the fault plane itself. For instance, in the Solitario Canyon Fault zone in the ECRB Cross Drift, the total displacement is approximately 260 m, but the gouge and brecciated zones are limited to less than 20 m. Similarly, the Dune Wash Fault as exposed in the ESF exhibits a cumulative offset of 65 m (Sweetkind et al. 1997 [DIRS 177047], Table 21), but the zone of increased fracture frequency in the vicinity of the fault is only 6 to 7 m wide. A third example is the observation of the Sundance Fault in the ECRB Cross Drift, where the footwall rock is intact, even within the 10 cm of the fault plane. The hanging wall is slightly more fractured, with an intensely fractured zone about 1 m thick. Consequently, an analysis of fault displacement should also consider a case where the effects of strain are limited to the immediate vicinity of the fault zone (Section I3.3.1).

I2.1.3 Fault Displacement Hazards

Fault displacement hazards at Yucca Mountain have been investigated in detail in *Probabilistic Seismic Hazard Analyses for Fault Displacement and Vibratory Ground Motion at Yucca Mountain, Nevada* (CRWMS M&O 1998 [DIRS 103731]). Several original approaches to characterizing the fault displacement potential were developed by the seismic source expert teams. The approaches were based primarily on empirical observations of the pattern of faulting at the site during past earthquakes (determined from data collected during fault studies at Yucca Mountain). Empirical data were fit by statistical models to allow use by the experts. The results of this analysis were curves representing probabilistic predictions of fault displacements.

Nine locations within the preclosure controlled area were identified to demonstrate the fault displacement methodology. The term “preclosure controlled area” is defined in DOE Interim

Guidance (Dyer 1999 [DIRS 105655]). These locations were chosen to represent the range of potential faulting conditions. Two of the nine sites each had four identified faulting conditions. Some of these locations lie on faults that may experience both principal faulting and distributed faulting. The other points are sites only of potential distributed faulting.

With the exception of the block-bounding Bow Ridge and Solitario Canyon Faults (sites 1 and 2, respectively), the mean displacements are 0.1 cm or less at a 10^{-5} annual exceedance probability, and on the order of 1 m or less at 10^{-8} annual exceedance probability (CRWMS M&O 1998 [DIRS 103731], Figures 8-4 through 8-14). For the Ghost Dance Fault, the range of displacements per event is 0.6 m to about 1.5 m at 10^{-8} mean annual exceedance probability (CRWMS M&O 1998 [DIRS 103731], Figure 8-5). Thus, sites not located on a block-bounding fault, such as sites on the intrablock faults, other small faults, shear fractures, and intact rock, are estimated to have displacements significantly less than 0.1 cm for mean annual exceedance probabilities of 10^{-5}.

For Solitario Canyon Fault and Bow Ridge Fault (CRWMS M&O 1998 [DIRS 103731], Figures 8-2 and 8-3), the mean displacements are 7.8 and 32 cm, respectively, for these two faults at a 10^{-5} annual exceedance probability. At lower annual exceedance probabilities, the fault displacement hazard results are driven by the upper tails of uncertainty distributions and are close to 10 m.

For purposes of determining the appropriateness of the chosen bounding conditions based on the Probabilistic Seismic Hazard Assessment, per-event displacements can be used as a comparison. As described in Section I2.1.1, the largest estimate of per event displacement for the faults intersected by the two-dimensional cross section used for the analysis is 1.4 m along the Solitario Canyon Fault. A displacement of 1.2 m corresponds to the 15th percentile curve at a 10^{-8} annual exceedance probability (CRWMS M&O 1998 [DIRS 103731], Figure 8-3). As described in Section I3.2.6, strains associated with a displacement of 10 m are used as bounding conditions. Given that the assumed bounding condition is about a factor of 10 greater than measured displacement and the probabilistic displacement event suggested by the 15th percentile curve, the values used in this analysis are judged to be extremely conservative.

I2.1.4 Climate Data

The primary controlling factor for flow through the unsaturated zone is the amount of infiltration through the system. This variable is highly dependent on precipitation and climate conditions. To address this constraint, present-day average and long-term average conditions were used as a representative range of future climate conditions.

Present-day climate conditions represent relatively dry, interglacial conditions, while the glacial-transition conditions represent typical conditions at Yucca Mountain between the wet and dry extremes based on available paleoclimate data (BSC 2004 [DIRS 170002], Table 6-1). Because these two sets of conditions represent relatively stable (that is, long-term conditions) rather than extreme conditions (that is, short-duration climatic states such as superpluvial periods), they were chosen as representative conditions for this analysis.

I3. EFFECTS OF FAULT DISPLACEMENTS ON UNSATURATED ZONE FLOW AND TRANSPORT

As discussed in Section I2, fault displacements are expected to occur along existing faults in the vicinity of Yucca Mountain. The movement produced by a fault displacement will result in changes in the rock stress in the vicinity of the fault. The change in rock stress will decrease with distance from any given fault that does move. However, the magnitude of the changes in rock stress as a function of distance from the fault depends on the specific details of the fault displacement (e.g., magnitude of fault motion, direction of fault movement, extent of the fault that participates in the movement) and the mechanical properties of the surrounding rock (e.g., fracture spacing, fracture stiffness, geomechanical properties of the rock matrix). Given some change in rock stress, the fractured rock mass will respond to the change in stress through deformation, or strain, in the rock. Of particular importance is the fact that this induced strain can affect the geometry of fractures in the rock. The effects of changes in properties of the rock matrix (as opposed to the fractures) are assumed to have a negligible effect on unsaturated zone flow and transport. Several fracture properties (permeability, capillary pressure, porosity) are a function of fracture aperture, which can be changed significantly by small strains if these strains are allocated entirely to the fracture apertures. The sensitivity of fracture aperture to mechanical strain is due to the small porosity of the fracture continuum. The matrix, on the other hand, has much greater porosity than the fractures in general, and its properties are not expected to be as sensitive to mechanical strain. This approximation is reasonable given the fact that fracture porosity is much less than matrix porosity at Yucca Mountain.

Some of the effects of previous fault displacements at Yucca Mountain can be examined directly. Previous fault displacements have resulted in observable changes to the structure of the surrounding rock (Section I2.1.1). However, geologic observations are not adequate to assess the effects of some of the changes caused by fault displacements that could be important to unsaturated zone flow and transport. In fact, it is difficult to determine the effective hydraulic apertures of the present-day fractures at Yucca Mountain by direct observation (Sonnenthal et al. 1997 [DIRS 101296], Section 7.5.4). Fracture apertures at Yucca Mountain are determined through pneumatic flow tests (giving the fracture permeability) and a theoretical model relating fracture frequency (determined by observation of fractures), fracture permeability, and fracture aperture (Sonnenthal et al. 1997 [DIRS 101296], Section 7.5.4).

I3.1 ANALYSIS APPROACH

A bounding approach is used to assess the potential effects of fault displacement on repository performance. The problem is bounded if large enough changes in fracture aperture are evaluated. Here, "large enough changes" are defined to be changes that can be justified as larger than any expected changes resulting from any fault displacements (near Yucca Mountain) that have an annual exceedance probability greater than 10^{-8} (SNL 2008 [DIRS 179476], Section 6.2, *Low Probability Criteria*). Given an assumed change in aperture, it is possible to estimate the change in fracture hydraulic properties using theoretical models that relate the changes in fracture properties to the changes in fracture aperture (Section I3.2.3). Effects of the modified fracture properties on transport behavior between the repository and the water table can be evaluated using the UZ site-scale flow and transport models. Changes in transport are identified through the use of breakthrough curves for a simulated nonsorbing tracer. Transport of a

nonsorbing tracer is used because this is expected to be more sensitive to changes in fracture aperture, because the effects of fracture aperture dominate fracture-matrix interaction for such a tracer (given fixed matrix properties).

In theory, the effects of a given fault displacement could be evaluated using process-level calculations for the effects of the induced stress and strain on fracture geometry. Then the effects of this change in fracture geometry on the fluid-flow properties of the fracture network could be evaluated. However, this method was not used in this analysis due to the large uncertainty in rock mechanical properties and models relating fault displacement induced changes in stress to changes in fracture apertures on the scale of unsaturated zone model domain.

If the identified changes in transport are small, then it can be concluded that the effects of fault displacement on potential radionuclide transport are negligible and can be excluded from further consideration in TSPA.

The spatial distribution of changes to fracture aperture within the modeling domain is treated using two end-member scenarios:

1. All fracture apertures are altered uniformly throughout the unsaturated zone model domain (fault zones and fractured rock).

2. Only fracture apertures in the fault zones are altered.

Isolating the effects of fault displacement to the fault zones provides the most reasonable expected case, which emphasizes the effects of property contrasts between the fault zones and the fractured rock. A large change in fracture properties over the entire unsaturated zone domain (fault zones and fractured rock) is an extreme bound for the possible effects of fault displacement. These cases bound the expected extremes for the spatial distribution of changes to fracture properties as a result of fault displacement.

Sensitivity calculations are performed for both the present-day (dry) climate and the long-term, glacial-transition (wetter) climate. The average infiltration rates used in the TSPA-SR UZ flow model for the present-day mean climate is about 4.6 mm/yr and for the glacial-transition mean climate is about 18 mm/yr (BSC 2004 [DIRS 169861], Table 6.1-2). The water table elevation remains unchanged in this analysis as a result of fault displacement or climate change. Maintaining a fixed water table provides a reference point for comparisons of the effects of fault displacements on radionuclide transport. This is reasonable as a basis for comparison of the effects of fault displacement.

Fault displacements may result in changes to perched water. However, the effects of these changes in perched water on potential radionuclide transport are assumed to be negligible. The sensitivity of radionuclide transport to different perched water models has been shown to be small (CRWMS M&O 2001 [DIRS 158726], Section 6.7.3). Furthermore, the potential release of the perched water (and associated radionuclides) due to some disruptive event is expected to have a negligible effect on radionuclide releases at the water table (FEP 2.2.06.03.0A (Seismic Activity Alters Perched Water Zones)). Therefore, any additional changes in perched water, except for those changes caused by changes in fracture properties, are not expected to have significant consequences.

Thermal-hydrologic processes due to waste heat from the repository will affect unsaturated zone flow and transport. However, the effects of thermal-hydrologic processes are expected to be negligible with respect to this sensitivity study on the effects of fault displacements on mountain-scale unsaturated zone transport (FEP 2.2.12.00.0A (Undetected Features in the UZ)).

I3.2 USE OF SITE RECOMMENDATION MODEL

In this work, steady-state flow fields with fracture apertures undisturbed or changed (to represent the effects of seismic activity) were first calculated, and then used to run transport simulations. A steady-state flow field had previously been calculated for the site recommendation model (BSC 2004 [DIRS 169861], Section 6.2.3), and this result provided a flow field that could be used as an initial condition to determine the steady state flow fields for these calculations. For this reason these calculations were done using the site recommendation model. The site recommendation and license application models are similar enough that use of the site recommendation model instead of the license application model is appropriate for the purpose of determining the sensitivity of transport to fracture aperture, as will be shown below. The site recommendation and license application flow and transport models are based on the same dual-permeability/active fracture conceptual model and numerical implementation. A significant difference between the models is the shift in repository footprint to the north for the license application case compared with the site recommendation design and some limited changes in parameterization based on new calibrations for the license application case.

Transport results for present-day and glacial-transition climate scenarios are compared in Figures I-1 and I-2. The transport results are for a uniform, instantaneous release of tracer mass from all repository locations at time zero. The tracer is nonsorbing, but can diffuse into the matrix. The present-day scenarios are shown in Figures I-1a and I-1b, which present the fractional cumulative breakthrough curves and average curves, respectively. The average curves are the weighted averages of the site recommendation and license application scenarios. For site recommendation, the weighting factors are 0.24, 0.41, and 0.35 for lower, mean, and upper cases, respectively (BSC 2003 [DIRS 165991], Table 7-1). Note that the "mean" case is not a statistical mean, but is an intermediate case between the upper and lower cases. For license application, the weighting factors are 0.62, 0.16, 0.16, and 0.06 for the 10th percentile map, 30th percentile map, 50th percentile map, and 90th percentile map cases, respectively (SNL 2007 [DIRS 184614], Table 6.8-1). For a unit tracer released at the repository at time zero, the fractional breakthrough curve represents the tracer cumulative arrival at the water table as a function of time. The glacial-transition scenarios are shown in Figures I-2a and I-2b, which present the fractional cumulative breakthrough curves and average curves, respectively. The weighting factors are the same as used for the present-day, both for site recommendation and license application. These curves show that differences between site recommendation and LA are small in comparison with the uncertainty for each climate. The goal of the present analysis is to compare the relative effects of changes in fracture aperture on unsaturated zone transport behavior. Because the conceptual and numerical models for the site recommendation and license application models are nearly the same, and the responses for unsaturated zone transport are similar, the site recommendation model is suitable for its intended use of assessing transport sensitivity to seismic-induced changes in fracture properties.

I3.2.1 Problem Domain and Site-Scale Flow and Transport Models

The three-dimensional, site-scale UZ flow and transport model domains are shown in plan view in Figures I-3a and I-3b for the site recommendation and license application models, respectively (BSC 2001 [DIRS 158726], Figure 6-2; SNL 2007 [DIRS 184614], Figure 6.1-1). These figures indicate the differences in gridding and repository locations. Despite these differences, calculation results shown in Section I.3.3 indicate that transport behavior is similar for the two models. In both model grids, faults are represented by vertical or inclined 30-m-wide zones. Although major faults, such as Solitario Canyon Fault, can be wider than 30 m, transport behavior is not sensitive to the width of the fault because of the larger capacity of the faults for conducting water flow.

The site-scale UZ flow model computes unsaturated flow over the model domain. In this model, fractured rock is represented using an active-fracture dual-permeability conceptual model. Transport simulations in this appendix use conservative tracers. The dual-permeability modeling approach using the same three-dimensional TSPA-SR grid is used in the transport simulations. The fracture-continuum permeability and van Genuchten α values for these simulations were obtained from DTNs: LB990801233129.009 [DIRS 118717] and LB990801233129.003 [DIRS 122757]; the grid was obtained from DTN: LB990701233129.001 [DIRS 106785]. The use of these site recommendation rock properties and grid is justified for their intended use in Section I3.1. A discussion of the software used and more details concerning the flow and transport calculations are presented in DTN: LB0408U0170FEP.002 [DIRS 171596].

I3.2.2 Bounds on the Change in Fracture Aperture

The approach used to investigate the effects of fault displacements is to evaluate the sensitivity of radionuclide transport in the unsaturated zone to changes in fracture apertures. This is investigated over a wide enough range to bound the potential changes in fracture aperture that could result from any fault displacement at Yucca Mountain with an annual exceedance probability of greater than 10^{-8}. The largest fault movement close to the repository is likely to be along Solitario Canyon Fault. The general topic of seismic hazard at Yucca Mountain has been investigated in detail in *Probabilistic Seismic Hazard Analyses for Fault Displacement and Vibratory Ground Motion at Yucca Mountain, Nevada* (CRWMS M&O 1998 [DIRS 103731]). For Solitario Canyon Fault, the hazard analysis shows fault displacement of about 10 m (CRWMS M&O 1998 [DIRS 103731], Figure 8-3) at an annual exceedance probability of 10^{-8}.

Geomechanical models used to investigate the amount of strain induced by fault movements in the rock at Yucca Mountain show that changes in strain extend several kilometers from a fault movement (Gauthier et al. 1995 [DIRS 103258]; National Research Council 1992 [DIRS 105162], Appendix D). Using a three-dimensional elastic boundary element model of Yucca Mountain, Gauthier et al. (1995 [DIRS 103258]) investigated the effects of a right-lateral, strike-slip fault displacement on a fault dipping 60° E. The fault movement was 1 m along a 30 km section of the fault. The results show strains of 10 microns per meter (10 micro-strain, or 10 μs) up to 8 km from the fault. Geomechanics calculations were also performed in the report by the National Research Council (1992 [DIRS 105162], Appendix D). This calculation was for a normal displacement along a fault dipping 60° E to the vertical. The simulated fault movement was 1 meter along 30 km section from the surface to a depth of 10 km. The results of this calculation show 50 μs two kilometers from the fault plane and 10 μs about 6 km from the fault plane. If these models were used for a 10-m fault movement instead of 1 m, the strains would be amplified proportionally because of the linearity of the elastic model. Therefore, for a bounding fault movement of 10 m along Solitario Canyon Fault, an elastic model would predict strains up to 500 μs two kilometers from the fault and 100 μs six kilometers from the fault. If the conservative approach is taken that all the strain accumulates in the fractures, then an estimate of the change in aperture can be made. First, assume a lower bound aperture of 100 μm in the present-day system (Sonnenthal et al. 1997 [DIRS 101296], Table 7.12) and a fracture spacing of approximately 1 m (Sonnenthal et al. 1997 [DIRS 101296], Table 7.7). Then a tensile strain of 500 μs would result in a new fracture aperture of about 600 μm. For a compressive strain of 500 μs, then the fractures would essentially be closed and the rock matrix would necessarily be compressed.

Changes in fracture properties are related to dilation or compression of existing fractures rather than the generation of new fractures. This approximation relies on the fact that the rock at Yucca Mountain is highly fractured and that fractured rock is mechanically weaker along existing fractures than intact rock. This assumption is supported by the results of the Probabilistic Seismic Hazard Analysis, which show that the probability for fault displacement to occur along existing fractures is more likely than for intact rock (CRWMS M&O 1998 [DIRS 103731], Section 8.2.1). Therefore, strain due to fault displacement is likely to occur along existing fractures rather than initiate new fractures.

I3.2.3 Affected Parameters

Given a change in aperture, theoretical models are available to quantitatively model the associated changes in fracture permeability, fracture capillary pressure, and fracture porosity. Fracture aperture enters flow and transport modeling in different ways. Aperture affects the permeability and capillary pressure used for steady-state unsaturated flow calculations. For radionuclide transport calculations, the fracture aperture affects the fracture porosity. Fracture aperture also affects matrix diffusion for radionuclide transport, but for these simulations the matrix diffusion coefficient was set to zero. The fracture apertures used in these different parameters are not necessarily the same because the theoretical models strictly apply to idealized "parallel plate" fractures. Therefore, the aperture for permeability, capillary pressure, and porosity are generally different values. However, it is assumed that an increase or decrease in aperture will affect these physical characteristics in proportion to the functional dependence on aperture in the theoretical models.

The relationship for permeability, known as the cubic law (Freeze and Cherry 1979 [DIRS 101173], Section 2.12; Sonnenthal et al. 1997 [DIRS 101296], Section 7.5.4), is the following:

$$k = \overline{f}\,\frac{b^3}{12} \qquad \text{(Eq. I-1)}$$

where $\overline{f}$ is the average fracture spatial frequency, k is the permeability, and b is the fracture aperture. As can be seen, the permeability is proportional to the cube of the fracture aperture.

The relationship between capillary pressure and saturation is derived from van Genuchten (1980 [DIRS 100610]), noting that $S_e = \Theta$ in van Genuchten's notation:

$$P_c = \frac{2\tau\cos\theta}{b\rho g}\left[S_e^{-1/m} - 1\right]^{(1-m)} \qquad \text{(Eq. I-2)}$$

where P_c is the capillary pressure (expressed as elevation above the water table by inclusion of ρ and g terms), τ is the surface tension of an air–water interface, θ is the contact angle between the air–water interface and the mineral surface, ρ is the density of water, g is the acceleration of gravity, S_e is the effective water saturation (normalized for the residual and maximum saturations), and m is a parameter describing the variation in capillary pressure with water saturation.

The collection of terms, $\frac{b\rho g}{2\tau\cos\theta}$, is known as the van Genuchten α parameter. The van Genuchten α parameter scales the overall capillary pressure in the system. The parameter m accounts for the distribution of fracture apertures that the air–water interface encounters as a function of water saturation. The van Genuchten α parameter is directly proportional to fracture aperture.

The relationship for porosity, ϕ_f, is the following:

$$\phi_f = \overline{f} b \quad \text{(Eq. I-3)}$$

The porosity is also found to be proportional to the fracture aperture.

Now, let b be changed to b^* ; then correspondingly k, α, and ϕ_f, are changed to k^*, α^*, and ϕ_f^*. These variables can be used to express the following relationships:

$$k^* = (b^* / b)^3 k \quad \text{(Eq. I-4)}$$

$$\alpha^* = (b^* / b)\alpha \quad \text{(Eq. I-5)}$$

$$\phi_f^* = (b^* / b)\phi_f \quad \text{(Eq. I-6)}$$

The factor of change in fracture aperture (b^*/b) is then used to directly assign the new values of permeability, capillary pressure (α), and porosity.

In addition, the volumes for fracture and matrix elements should also be varied to reflect changes in fracture porosity . Assume V_f and V_m as the original fracture and matrix element volumes, then the fracture and matrix element volumes varied due to fracture aperture change can be calculated as:

$$V_f^* = V_f(\phi_f^* / \phi_f) \quad \text{(Eq. I-7)}$$

$$V_m^* = V_m(1 - \phi_f^*)/(1 - \phi_f) \quad \text{(Eq. I-8)}$$

Such variation in fracture and matrix element volumes only changes the partition of the bulk grid-cell volume (into either V_f and V_m or V_f* and V_m*), which itself remains as a constant.

I3.2.4 Calculation Procedures

Steady-state flow fields for single-phase, unsaturated flow are obtained through transient flow simulations to steady-state conditions. Transport calculations are then performed using the steady-state flow fields.

The matrix and fracture parameter values both for the hydrogeologic units and the faults are taken from the TSPA-SR base-case UZ flow model (BSC 2004 [DIRS 169861]) and treated as the base case for this study. Sensitivity cases are conducted using fracture apertures modified as discussed in Section I3.2.3. Flow and transport modeling calculations are performed for present-day and glacial-transition climates. The unsaturated zone flow results from the base-case unsaturated zone flow calculation are processed to obtain the initial condition for calculations involving cases affected by fault displacement.

Based on the cubic law for fracture permeability (Section I3.2.3), a change of a factor of 10 in aperture leads to a change of a factor of 1,000 in permeability. Fracture permeabilities reduced

by a factor of 1,000 were found to be inconsistent with the infiltration rates imposed on the model, because the bulk permeability was insufficient to accommodate the flow conditions. So, either reduced infiltration rates or a smaller reduction factor for the aperture would need to be used. Because the reduced apertures lead to reduced transport rates, this sensitivity does not show a potential adverse impact on performance. A lower-bound reduction in aperture of a factor of 0.2 is considered sufficient. Therefore, a change in fracture aperture by a factor of 0.2 to 10 was used in this sensitivity analysis.

The input and output files for the calculations presented in Section I3.3 are documented under DTNs: LB0408U0170FEP.001 [DIRS 171595] and LB0408U0170FEP.002 [DIRS 171596].

Unsaturated zone flow properties affected by fracture aperture were varied for the sensitivity study reported in this analysis. For the unsaturated zone transport calculations, diffusivity was given a nominal value of 3.2×10^{-11} m^2/s, with a tortuosity of 0.7, for an effective diffusivity of 2.24×10^{-11} m^2/s, as discussed in *UZ Flow Models and Submodels* (BSC 2004 [DIRS 169861], Sections 6.5.2 and 6.7.1). Only nonsorbing transport is investigated here. Dispersion has been shown to have little effect on transport results in the unsaturated zone over a wide range of dispersivities investigated (BSC 2004 [DIRS 169861], Section 6.8.2.1). Therefore, a dispersivity of zero was assigned because ignoring the process of dispersion is not expected to influence the comparison of results.

I3.3 RESULTS

The next two sections describe the effects of fracture aperture changes on unsaturated zone flow and transport between the repository and the water table. Results for cases in which the fracture apertures are varied are compared with the corresponding base cases. Section I3.3.1 considers a three-dimensional model when fracture apertures are only changed in the fault zones. Section I3.3.2 describes the results for transport in a three-dimensional model with fracture apertures changed both in the fault zones and in the fractured rock (uniformly across the entire repository block). These three-dimensional calculations are performed for present-day and the glacial-transition climates. Mass transport calculations correspond to the instantaneous release of tracer mass at the repository at time zero.

I3.3.1 Fracture Apertures Altered in Fault Zones Only; Three-Dimensional Calculations for Present-Day and Glacial-Transition Climates

In this set of calculations, only the fracture apertures for the fault zones are changed by given factors. The flow and transport calculations results shown in this section were performed as described in Section I3.2.4.

As shown in Figures I-4 and I-5, respectively, for the present-day climate and the glacial-transition climate, the breakthroughs for the altered cases remain essentially unchanged from the base case. This indicates that if only the fault fracture apertures are affected by factors of 0.2 to 10, there would be virtually no impact to unsaturated zone flow and transport. The normalized mass arrival rate in these figures is the time-derivative of the breakthrough curve.

Figure I-5. Breakthrough Curves under Glacial-Transition Infiltration When Fracture Property Changes Are Limited to the Fault Fractures

I3.3.2 Fracture Apertures Altered Uniformly Across the Repository Block; Three-dimensional Calculations for Present-Day and Glacial-Transition Climates

The three-dimensional flow and transport calculations described in this section were performed as described in Section I3.2.4. The breakthrough curves for the present-day and the glacial-transition climates are shown in Figures I-6 and I-7, respectively. The results exhibit much greater influence compared with the case in which fracture property changes are confined to the fault zones. For the factor-of-10 case, travel time (for 0.5 fractional breakthrough) is found to decrease by about a factor of 25 for the present-day case and a factor of 11 for the glacial-transition climate. On the other hand, the normalized mass arrival rates are likely to be more significant for dose because the rate of radionuclide mass arrival at the accessible environment is what controls dose rates. Comparisons between peak (maximum) mass arrival rates for present-day and glacial-transition show that the effects of fault displacement are about a factor of 1.4 and 1.3, respectively. Furthermore, the peak doses occur slightly later for the $\times 10$ aperture case. For the $\times 0.2$ aperture case, the breakthrough curves are significantly delayed relative to the base case and the peak mass arrival rate is reduced by substantially more than one order of magnitude.

I3.4 Discussion

The effect of changing fracture apertures on mass transport reflects the trend observed in the effect on flow; increased aperture leads to greater transport in fractures and shorter travel time to the water table. This leads to a consistent trend for simulated tracer breakthrough profiles at the water table. If the fracture apertures are decreased, the travel times of the majority of the particles are increased, causing delayed breakthrough. Similarly, if the fracture apertures are increased, the travel times of the majority of the particles are decreased, causing earlier breakthrough. In particular, when fracture apertures are increased, the travel times of some particles are decreased due to enhanced transport in the fractures.

Capillary and gravity forces in the fractures of the dual-permeability model tend to work against fracture-matrix inter-flow and keep water flowing in the fractures. Note that fracture-matrix inter-flow is driven by the matrix-fracture capillary pressure difference. Assuming the inter-flow is from the fractures to the matrix, larger fracture apertures tend to promote fracture-to-matrix flow due to decreased fracture capillary pressure (that is, increased matrix-fracture capillary pressure differential). On the other hand, as fracture aperture is increased, gravity exerts more effect to keep flow within the fractures. The decreased capillary pressure in the fractures is roughly inversely proportional to the fracture aperture. In addition, due to the use of upstream weighting of the relative permeability in the numerical scheme, the fracture relative permeability is used with the matrix absolute permeability to estimate the effective permeability of the fracture-matrix interface for fracture to matrix flow. The fracture relative permeability is the effective permeability for the fracture system at the given flow rate divided by the absolute permeability of the fracture system (i.e., a saturated fracture system). Thus, when the fracture apertures are increased, the fracture relative permeability (for about the same amount of fracture flow) decreases roughly in proportion to the cube of the aperture ratio. This is because the effective permeability is roughly set by the amount of flow and the saturated permeability is proportional to the cube of the fracture aperture (Equation I-1). Therefore, the fracture-matrix interface effective permeability is also reduced by this ratio. This reduction of the fracture-matrix interface effective permeability leads toward greater flow and transport in the fractures when fracture apertures are increased. The above mechanism for enhanced fracture transport when fracture aperture is increased is further promoted by the use of active-fracture dual permeability model. This is because under the active fracture model, liquid flow occurs only over a fraction of fracture-matrix interface area, thus resulting in reduced fracture-matrix transport and increased transport through the fractures.

I4. CONCLUSIONS

This study addresses the potential effects of fault displacement on transport in the unsaturated zone using sensitivity analysis that is conducted by perturbing fracture parameters. The degree of such perturbations is conservatively based on assessment of the geological information of the site.

The sensitivity studies for unsaturated zone flow and transport presented in this analysis suggest that changes in fracture aperture confined to the fault zones show virtually no effect on transport behavior. For an extremely conservative ten-fold increase in fracture aperture applied over the entire unsaturated zone domain, breakthrough is found to be about 25 times earlier for

present-day infiltration and about 11 times earlier for glacial-transition infiltration. Nevertheless, changes in the peak mass arrival rate at the water table are much smaller, factors of 1.4 and 1.3 for present-day and glacial-transition climates, respectively. Effects of such magnitude on travel time and mass arrival rates are no more significant than those caused by uncertainties in infiltration (Figures I-1 and I-2). In addition to infiltration uncertainty, the unsaturated zone radionuclide transport model used for TSPA samples uncertain transport parameters (SNL 2008 [DIRS 184748], Addendum Sections 6.5.5 and 6.5.6, and Section 6.5.7). Therefore, the uncertainty in unsaturated zone radionuclide transport incorporated in the TSPA is greater than the uncertainty in transport that results from infiltration uncertainty. Given the relatively limited changes found for the extremely conservative change in properties over the entire domain, the effects of fault displacement on unsaturated zone transport are expected to be negligible. Therefore, models for TSPA-LA may exclude the effects of fault displacement on unsaturated zone transport as discussed in FEPs 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults) and 2.2.06.02.0B (Seismic Activity Changes Porosity and Permeability of Fractures).

APPENDIX J

QUALIFICATION OF DATA AND JUSTIFICATION OF EQUATIONS

This appendix presents the qualification of project and external data for intended use as direct input as well as the justification of equations used in excluded FEPs.

J1. DATA TO BE QUALIFIED

SCI-PRO-004, *Managing Technical Product Inputs*, categorizes technical product input usage as either direct input or indirect input. Direct input is used to develop the results or conclusions in a technical product. Indirect input is used to provide additional information that is not used in the development of results or conclusions. If not classified as established fact, unqualified data acquired or developed by Yucca Mountain Project (YMP) participants (project data) used as direct input to excluded FEPs must be qualified; external source data may be qualified for intended use within a given FEP's screening justification. Equations are justified for intended use in accordance with Attachment 2 Item 4 of SCI-PRO-005, *Scientific Analyses and Calculations*. Data (project and external source) are qualified for intended use in accordance with SCI-PRO-005, Section 6.2.1.M.3. Table J-1 lists the sources of the data to be qualified. A copy of the data qualification plan for project data and external source data can be found at the end of this appendix as Figure J-1. The summary of data to be qualified for intended use, that is part of the data qualification plan, is shown in Table J-2.

The data presented in this appendix were qualified by considering one or more of the data qualification methods provided in Attachment 3 of SCI-PRO-001, *Qualification of Unqualified Data*. The data qualification process included an initial evaluation of the data quality and correctness. The data qualification team evaluated the data by comparing the methods used to plan, collect, and analyze the data against generally accepted scientific or engineering practices. It was determined that the data were adequate and the method was implemented and documented within this appendix. The members of the qualification team are independent of the data set to be qualified. The qualification process attribute(s) that were appropriate for the data under consideration are listed for each data being qualified; data evaluation criteria were based on qualitatively or quantitatively meeting process attributes by the data under consideration.

In this appendix, data are examined on a FEP-by-FEP basis. Data are qualified for intended use for the FEP in which the data are used as direct input. This appendix is organized in subsections listed sequentially by FEP number.

J2. FEP 1.1.02.00.0B – MECHANICAL EFFECTS OF EXCAVATION AND CONSTRUCTION IN EBS

This FEP uses data from the following report as direct input:

Craig, R.W. 2001. "Transmittal of Level 5 Deliverable SPW205M5, 'Excavation-Induced Fracture Study'." Letter from R.W. Craig (USGS) to T.C. Gunter (DOE/YMSCO), September 26, 2001, with enclosure. ACC: MOL.20011114.0003. [DIRS 171411]

The data to be qualified for intended use within this FEP include:

> Energy is focused on the rock to be removed, so that excess energy is not dispersed into the surrounding rock, as from blasting (Craig 2001 [DIRS 171411], pp. 1, 3, and 8).
>
> Examination of the tunnel walls and associated alcoves, niches, and drillholes has been used to define the character and extent of mechanical damage induced by tunnel boring (Craig 2001 [DIRS 171411], pp. 3 to 11, and 16).
>
> In rock with few fractures, the tunnel boring machine-induced fracturing of the tunnel periphery is confined to a depth of influence of less than 5 centimeters (Craig 2001 [DIRS 171411], p. 16).

J2.1 QUALIFICATION METHOD

The method of qualification of the data from Craig (2001 [DIRS 171411]) listed above is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data and their existing documentation. The technical assessment included determination that the employed methodology was acceptable, determination that confidence in the data acquisition or development was warranted, and confirmation that the data had been used in similar applications. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and reliability of the documentation associated with the data (#9).

J2.2 TECHNICAL ASSESSMENT

Qualifications of Personnel or Organizations Generating the Data—The excavation-induced fracture study was conducted by members of the U.S. Bureau of Reclamation Underground Geologic Mapping team, for which Steve Beason was the principal investigator. The U.S. Bureau of Reclamation is one of the government agencies responsible for geologic mapping of federal projects, particularly dam sites and tunnels, and has provided engineering geologic services to the DOE and USGS for characterization of the Yucca Mountain site since the mid-1980s. The YMP geologists from the U.S. Bureau of Reclamation mapped approximately 10 km of underground tunnels at Yucca Mountain, including the ESF and the Enhanced Characterization of the Repository Block (ECRB) Cross-Drift, between 1994 and 1997. The team subsequently compiled their findings in completion reports for the various excavations (e.g., Albin et al. 1997 [DIRS 101367]; Eatman et al. 1997 [DIRS 157677]).

Technical Adequacy of Equipment and Procedures Used—The data collection method consists of recording visual observations made by the mapping geologists in a scientific notebook, which in turn is technically reviewed. This method is typical of geologic investigations; it is prescribed through the procedure that governed the underground mapping, U.S. Geological Survey Procedure YMP-USGS-GP-32, *Underground Geologic Mapping*.

Extent and Reliability of the Documentation Associated with the Data—The underground excavation observations were made and recorded in a scientific notebook (Beason 2003 [DIRS 171953], pp. 77 to 80), following the then-current YMP procedure AP-SIII.1Q, *Scientific Notebooks*, which incorporated the quality assurance requirements of *Quality Assurance Requirements and Description* (DOE 2004 [DIRS 171539], Supplement III), and, by extension, the requirements of 10 CFR 60, Subpart G [DIRS 100015]. A scientific notebook procedure has been used on the YMP since 1996. The Beason notebook (2003 [DIRS 171953], pp. 77 to 81) documents the scientific observations, the person who entered the data in the notebook and the technical review of the notebook entry.

Extent to Which the Data Demonstrate the Properties of Interest—The data were collected to compare the relative excavation effects of different mining techniques, including use of the tunnel boring machine, alpine miner, and drill and blast techniques. This FEP specifically uses the observations derived from the tunnel boring machine excavations. The observations directly relate to concerns regarding ability to maintain the circular cross-section of a tunnel-boring machine tunnel, depth of damage, and significance of the damage to modeling studies.

Data Have Been Used in Similar Applications—The underground tunnel data collected by the U.S. Bureau of Reclamation mapping team has been used extensively for YMP performance assessment and facility layout. The geologic and fracture data provide input into the hydrologic models for the unsaturated zone, and the information obtained regarding the mechanical stability of the rock has been used to determine the extent and orientation of the underground facilities.

J2.3 DATA QUALIFIED FOR INTENDED USE

The data from Craig (2001 [DIRS 171411]) cited above are appropriate for the intended use within FEP 1.1.02.00.0B (Mechanical Effects of Excavation and Construction in EBS). The technical assessment of these data provides sufficient confidence that the data meet qualification criteria outlined above and can be considered qualified for intended use within this FEP.

J3. FEP 1.2.01.01.0A – TECTONIC ACTIVITY – LARGE SCALE

This FEP uses data from the following report as direct input:

Fridrich, C.J.; Whitney, J.W.; Hudson, M.R.; and Crowe, B.M. 1998. *Space-Time Patterns of Late Cenozoic Extension, Vertical-Axis Rotation, and Volcanism in the Crater Flat Basin, Southwest Nevada.* Open-File Report 98-461. Denver, Colorado: U.S. Geological Survey. ACC: MOL.19981014.0299. [DIRS 164051]

The data to be qualified for intended use within this FEP include:

> During the period of peak tectonism (approximately 11.6 million years ago (Ma) to 12.7 Ma), the western part of Crater Flat basin subsided due to the basin extending from 18% to 40% in 1.1 million years or less (Fridrich et al. 1998 [DIRS 164051], p. 1).
>
> After 11.6 Ma, the rate of extension in the basin declined in a roughly exponential manner. The late Quaternary rate of extension is less than 1% of the initial rate (Fridrich et al. 1998 [DIRS 164051], pp. 1 and 13) and may be as low as 0.1% to 0.2% per million years (Fridrich et al. 1998 [DIRS 164051], pp. 19 and 20).
>
> The pattern of Quaternary deformation mimics the pattern of middle Miocene activity, but at substantially lower rates (Fridrich et al. 1998 [DIRS 164051], pp. 1 and 2).

J3.1 QUALIFICATION METHOD

Method 5, Technical Assessment, from Attachment 3 of SCI-PRO-001 is used for qualification of the data identified above. The rationale for using this method is that it was the most suitable considering the data and their existing documentation. The technical assessment included determination that the employed methodology was acceptable and determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).
- Prior peer or other professional reviews of the data and their results (#8).

J3.2 TECHNICAL ASSESSMENT

The methodology to estimate extension rates are (1) extension in the Miocene bedrock estimated by using the measure of stratal tilting and assuming a tilting domino model, (2) where data permitted the estimates were checked by use of reconstructed cross sections drawn perpendicular to the average strike of extensional faults, and (3) late Quaternary extension was estimated by summing the horizontal components of Quaternary fault displacements along transects

perpendicular to the strikes of major extensional faults (Fridrich et al. 1998 [DIRS 164051], p. 8). Quaternary fault displacement data were from mapping, trenching, and geochronologic studies (Fridrich et al. 1998 [DIRS 164051], p. 7). These methods are typical and well known in structural geologic studies and are used with assumptions appropriately employed for geologic studies of this type.

Standard geologic field methods and measurements were employed by individuals trained to these methods. Stratal tilt measurements (strike and dip) of compaction foliation in ash-flow tuffs were used to estimate the extension rate (Fridrich et al. 1998 [DIRS 164051], p. 6). These data were taken from geologic maps produced by Scott and Bonk (1984 [DIRS 104181]) and Faulds et al. (1994 [DIRS 105126]), supplemented by additional mapping completed by USGS geologist R. B. Scott as well as by Fridrich et al. (1998 [DIRS 164051]). To evaluate the reliability of stratal tilt data taken from compaction foliations, these data were compared against stratal tilt data taken from bedding in the same stratigraphic sections where possible (Fridrich et al. 1998 [DIRS 164051], pp. 6 to 7).

This study and the data it produced were part of an earlier publication (Fridrich et al. 1996 [DIRS 105086]). This earlier version was technically reviewed by two USGS geologists who are regarded as experts in the field of mapping pyroclastic deposits and tectonics of the southern Great Basin and Death Valley region (Fridrich et al. 2003 [DIRS 184915]). All technical comments were satisfactorily resolved.

J3.3 DATA QUALIFIED FOR INTENDED USE

The data from the report by Fridrich et al. (1998 [DIRS 164051]) concerning the rate of extensional tectonics and patterns of deformation since Miocene time (late Quaternary) are appropriate for intended use within FEP 1.2.01.01.0A (Tectonic Activity – Large Scale). The technical assessment presented above provides sufficient confidence that these data meet qualification criteria outlined above and can be considered qualified for intended use within this FEP.

J4. FEP 1.2.04.02.0A – IGNEOUS ACTIVITY CHANGES ROCK PROPERTIES

This FEP uses data from the following synthesis report as direct input:

CRWMS M&O 1998. *Synthesis of Volcanism Studies for the Yucca Mountain Site Characterization Project.* Deliverable 3781MR1. Las Vegas, Nevada: CRWMS M&O. ACC: MOL.19990511.0400. [DIRS 105347]

The data to be qualified for intended use within this FEP include:

> Laboratory analytical data and field observations of mineral alterations around igneous intrusions at natural analogue sites show that alteration extends less than 10 m away from the intrusion–host rock contact. Natural analogue studies in similar host rocks at the Nevada Test Site show that alteration is limited to a zone less than 10 m away from the intrusion/host rock contact (CRWMS M&O 1998 [DIRS 105347], pp. 5-41 through 5-71).

The CRWMS M&O (1998 [DIRS 105347]) report summarizes the Yucca Mountain site characterization data that include the results of natural analogue studies of basaltic intrusions and related alteration of surrounding host rock.

The data of interest are within Chapter 5 of the synthesis report, as indicated from the page numbers cited above. Because this is a synthesis report, the qualification of the data will be based on the source of the data, which is from Valentine et al. (1998 [DIRS 119132]). Valentine et al. (1998 [DIRS 119132]) studied two natural analogue sites: Paiute Ridge, Nevada, and Grants Ridge, New Mexico, and concluded that contact metamorphism from intrusive dikes is generally confined to distances of a few meters around the dike.

Valentine, G.A.; WoldeGabriel, G.; Rosenberg, N.D.; Carter Krogh, K.E.; Crowe, B.M.; Stauffer, P.; Auer, L.H.; Gable, C.W.; Goff, F.; Warren, R.; and Perry, F.V. 1998. "Physical Processes of Magmatism and Effects on the Potential Repository: Synthesis of Technical Work Through Fiscal Year 1995." Chapter 5 of *Volcanism Studies: Final Report for the Yucca Mountain Project.* Perry, F.V.; Crowe, B.M.; Valentine, G.A.; and Bowker, L.M., eds. LA-13478. Los Alamos, New Mexico: Los Alamos National Laboratory. TIC: 247225. [DIRS 119132]

In support of the data described above, the following data will be qualified for intended use:

> Mineral alterations around igneous intrusions at natural analogue sites show that alteration is limited to a zone that extends less than 10 m away from the intrusion/host rock contact (Valentine et al. 1998 [DIRS 119132], p. 5-74).

J4.1 QUALIFICATION METHOD

The method of qualification of the data listed above from Chapter 5 of the synthesis report (CRWMS M&O 1998 [DIRS 105347]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data and their existing documentation. The technical assessment included

determination that the employed methodology was acceptable and determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J4.2 TECHNICAL ASSESSMENT

Qualifications of Personnel or Organizations Generating the Data—Dr. Greg A. Valentine led the Hydrology, Geochemistry, and Geology Group at Los Alamos National Laboratory from 2001 until 2008, at which time he accepted a faculty position at SUNY Buffalo in the Department of Geology. He served for five years as the technical lead for igneous consequences at the YMP. His fields of research include numerical simulation of flow in porous media, explosive volcanic eruptions, and magma chamber dynamics. His field studies are related to volcanic hazards assessment, large-volume pyroclastic eruptions, fossil hydrothermal systems, and intrusion mechanisms and dynamics. Dr. Valentine received his Ph.D. in Geological Sciences (1988) from the University of California, Santa Barbara, and B.S. in Geological Engineering and Geology (1984) from the New Mexico Institute of Mining and Technology.

Technical Adequacy of Equipment and Procedures Used—The authors of the study (CRWMS M&O 1998 [DIRS 105347], Chapter 5; Valentine et al. 1998 [DIRS 119132]) used mineral analysis by x-ray diffraction and elemental analysis by neutron activation analysis to determine the extent of contact metamorphism. These are standard analytical techniques and generally accepted scientific practice for these analyses. Depletion of volatile elements near the contact was taken as evidence of metamorphism.

Data Demonstrate the Properties of Interest—The data from Valentine et al. (1998 [DIRS 119132]) show that the hydrologic effect of an igneous intrusion into unsaturated tuff is limited in extent. The theoretical basis for this is provided by the corroborating data.

Extent and Quality of Corroborating Data—The conclusions regarding the extent of rock property changes around igneous intrusions were based on two analogue studies. One of these two studies was subsequently reported by WoldeGabriel et al. (1999 [DIRS 110071]), who studied the effects of a basaltic intrusion at Grants Ridge, New Mexico, on the country rock, consisting of silicic tuffs and volcaniclastic sediments. The field and laboratory data were the

same as those reported by Valentine et al. (1998 [DIRS 119132]) and indicated that the physical changes due to the thermal effects of the intruded plug were confined to within 10 m of the plug.

WoldeGabriel et al. (1999 [DIRS 110071]) provide experimental evidence of limited extent of contact metamorphism and a theoretical explanation, supported by results of numerical simulation, of why the effects of igneous intrusion into unsaturated tuff are localized. A one-dimensional (radial) conductive model was verified against analytical solution and the code FEHM. Results of the numerical simulations are presented in WoldeGabriel et al. (1999 [DIRS 110071], Figures 9 and 13). These results show that 10 m away from the intrusion, the maximum temperature reached was 500°C; 600°C was only reached within 4 m of the intrusion. This localized effect is explained by the fact that the rock was unsaturated at the time of the intrusion. The lack of sufficient water prevents fluid-driven convective heat transfer, hydrothermal circulation, and extensive alteration of the country rock.

The numerical simulation of an analogue site corroborates the evidence that contact metamorphism from an intrusive dike is limited to within 10 m from the dike.

J4.3 DATA QUALIFIED FOR INTENDED USE

The data on rock alteration in the vicinity of igneous intrusions obtained from *Synthesis of Volcanism Studies for the Yucca Mountain Site Characterization Project* (CRWMS M&O 1998 [DIRS 105347], pp. 5-41 through 5-71) are adequate for intended use within FEP 1.2.04.02.0A (Igneous Activity Changes Rock Properties). The data from Valentine et al. (1998 [DIRS 119132], p. 5-74) describing the extent of rock alteration are the same data; they are used as direct input in FEP 1.2.10.01.0A (Hydrologic Response to Igneous Activity) (see FEP 1.2.10.01.0A in this appendix). The technical assessment of these data provides sufficient confidence that these data meet qualification criteria outlined above and can be considered qualified.

J5. FEP 1.2.05.00.0A – METAMORPHISM

This FEP uses data from the following references:

Petrology, Igneous, Sedimentary, and Metamorphic (Ehlers and Blatt 1982 [DIRS 167802])

Emplacement of Shallow Dikes and Sills Beneath a Small Basaltic Volcanic Center – The Role of Pre-Existing Structure (Paiute Ridge, Southern Nevada, USA) (Valentine and Krogh 2006 [DIRS 177282]).

J5.1 QUALIFICATION OF DATA FROM EHLERS AND BLATT 1982

Ehlers, E.G. and Blatt, H. 1982. *Petrology, Igneous, Sedimentary, and Metamorphic.* New York, New York: W.H. Freeman and Company. TIC: 255657. [DIRS 167802]

The data being qualified are stated in the form of boundary conditions required for the onset of regional metamorphism.

> Conditions conducive to the onset of regional metamorphism correspond to temperature of 150 to 200ºC and pressures of 0.5 to 1 kilobars, which occur at depths of 4 to 5 km (Ehlers and Blatt 1972 [DIRS 167802], p. 566).
>
> The geothermal gradient at convergent plate boundaries may range from less than 10°C per km to greater than 25°C per km (Ehlers and Blatt 1982 [DIRS 167802], pp. 684 and 685).

These data are used in this FEP to define the lowest temperature and pressure required for the onset of metamorphism, for comparison against the temperature and pressure increases associated with existing burial rates and geothermal gradients at the Yucca Mountain site.

J5.1.1 Qualification Method

The method of qualification for intended use of the data from the publication by Ehlers and Blatt (1982 [DIRS 167802]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that corroborating data are available for comparison with the unqualified data set and any inferences drawn to corroborate the unqualified data can be clearly identified, justified and documented. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Extent to which the data demonstrate the properties of interest (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J5.1.2 Corroborating Data

The direct input for this FEP is taken from the publication by Ehlers and Blatt (1982 [DIRS 167802]), largely because the values these authors present suggest the least temperature,

pressure, and depth of burial needed for the onset of regional metamorphism (i.e., conservative bounding conditions for onset). Using these conditions as the basis of the FEPs screening is, therefore, conservative. The data from this publication are corroborated by the data presented by other authors (Hyndman 1972 [DIRS 150295], pp. 270 and 272; Press and Siever 1978 [DIRS 167965], pp. 303; Retallack 1991 [DIRS 167870], p. 200).

Ehlers and Blatt (1982 [DIRS 167802], p. 566) indicate that 0.5 to 1 kbar is necessary for the onset of metamorphism, which is clearly conservative compared to the data published by Hyndman (1972 [DIRS 150295], p. 272), who indicates that 2 to 3 kbars of pressure are required. The onset temperature, 150°C to 200°C, given by Ehlers and Blatt (1982 [DIRS 167802], p. 566), is also clearly conservative and as much as one-half of that cited by the corroborating sources. Given the respective pressure gradients, Ehlers and Blatt (1982 [DIRS 167802], p. 566) would suggest metamorphic onset at depths as little as 1 to 2 km, but also indicate that a burial depth of 4 to 5 km is needed. In any case, these conditions are clearly conservative compared to the temperature and pressures, and to the depth of 10 km, based on Hyndman's information. They are also conservative compared to the 9-km depth based on the average thermal gradient, and they are conservative with respect to the onset temperatures presented by Press and Siever (1978 [DIRS 167965], p. 303). They are also more restrictive than the conditions indicated by Retallack (1991 [DIRS 167870], p. 200) of temperatures greater than 200°C and/or burial greater than 7 km.

For the FEPs analysis, all that is needed is to show that existing burial rates and geothermal gradients are insufficient to result in significant temperature and pressure increases. Therefore, a qualitative comparison of existing corroborating data is sufficient to support the intended use of the data as a conservative approach within this FEP.

J5.1.3 Data Qualified for Intended Use

The above literature review and corroboration of the direct input provides an acceptable level of confidence that the data are suitable for their intended use within FEP 1.2.05.00.0A (Metamorphism). The data identified above are qualified for use in the screening justification for this FEP.

J5.2 QUALIFICATION OF DATA FROM VALENTINE AND KROGH 2006

Valentine, G.A. and Krogh, K.E.C. 2006. "Emplacement of Shallow Dikes and Sills Beneath a Small Basaltic Volcanic Center – The Role of Pre-Existing Structure (Paiute Ridge, Southern Nevada, USA)." *Earth and Planetary Science Letters, 246,* 217-230. New York, New York: Elsevier. TIC: 258400. [DIRS 177282].

The data from this report to be qualified for intended use within this FEP include:

> In places the tuff is densely welded and forms black vitrophyre that grades rapidly away from the contact, over a distance of ~20 to 100 cm, into non-welded tuff that is apparently unaffected by the dike (Valentine and Krogh 2006 [DIRS 177282], p. 221).

J5.2.1 Qualification Method

The method of qualification of the data listed above from the journal article by Valentine and Krogh (2006 [DIRS 177282]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data and their existing documentation. The technical assessment included determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (# 1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (# 3).

- Prior peer or other professional reviews (# 8).

J5.2.2 Technical assessment

Qualifications of Personnel or Organizations Generating the Data—Dr. Greg A. Valentine led the Hydrology, Geochemistry, and Geology Group at Los Alamos National Laboratory from 2001 until 2008, at which time he accepted a faculty position at SUNY Buffalo in the Department of Geology. He served for five years as the technical lead for igneous consequences at the YMP. His fields of research include numerical simulation of flow in porous media, explosive volcanic eruptions, and magma chamber dynamics. His field studies are related to volcanic hazards assessment, large-volume pyroclastic eruptions, fossil hydrothermal systems, and intrusion mechanisms and dynamics. Dr. Valentine received his Ph.D. in Geological Sciences (1988) from the University of California, Santa Barbara, and B.S. in Geological Engineering and Geology (1984) from the New Mexico Institute of Mining and Technology.

Data Demonstrate the Properties of Interest—The data from Valentine and Krogh et al. (1998 [DIRS 177282]) show that the hydrologic effect of an igneous intrusion into unsaturated tuff is limited in extent, which is the property under consideration. The intended use of the data is to support the position that the scale at which permeabilities would change is limited to a few meters around the dike.

Prior Peer or Other Professional Reviews—The article under consideration was published in the professional, peer reviewed journal *Earth and Planetary Science Letters*. This journal publishes high-quality research articles in the area of geoscience, including lunar studies, plate tectonics, ocean floor spreading, and continental drift, as well as basic studies of the physical, chemical, and mechanical properties of the earth's crust and mantle, the atmosphere, and the hydrosphere.

J5.2.3 Data Qualified for Intended Use

The data related to spatial extent of changes in rock properties caused by the dike intrusion were also qualified for intended use in FEP 1.2.04.02.0A (Igneous Activity Changes Rock Properties). The list of authors of source references for those data includes Valentine and Krogh, the authors of the journal article that is the source of data for FEP 1.2.05.00.0A. The intended use of these data is the same for this FEP and for FEP 1.2.04.02.0A. See FEP 1.2.04.02.0A (Igneous Activity Changes Rock Properties) in this appendix for additional information regarding these data.

The technical assessment of the data on changes in permeability in the vicinity of igneous intrusions provides sufficient confidence that the relevant data (Valentine and Krogh 2006 [DIRS 177282], p. 221) are adequate for the intended use within FEP 1.2.05.00.0A (Metamorphism). The data identified above are qualified for use in screening justification for this FEP.

J6. FEP 1.2.06.00.0A – HYDROTHERMAL ACTIVITY

This FEP uses data from the following reports:

Geothermal Resource/Reservoir Investigations Based on Heat Flow and Thermal Gradient Data for the United States (Blackwell et al. 2000 [DIRS 183582])

Results of Borehole Monitoring in the Unsaturated Zone Within the Main Drift Area of the Exploratory Studies Facility, Yucca Mountain, Nevada (Rousseau et al. 1997 [DIRS 100178])

Origin, Timing, and Temperature of Secondary Calcite–Silica Mineral Formation at Yucca Mountain, Nevada (Wilson et al. 2003 [DIRS 163589]).

J6.1 QUALIFICATION OF DATA FROM BLACKWELL ET AL. 2000

Blackwell, D.D.; Wisian, K.W.; Richards, M.C.; and Steele, J.L. 2000. *Geothermal Resource/Reservoir Investigations Based on Heat Flow and Thermal Gradient Data for the United States.* DOE/ID/13504. Washington, D.C.: U.S. Department of Energy. ACC: LLR.20070919.0006. [DIRS 183582]

The data from this report to be qualified for intended use within this FEP include:

> In the Basin and Range province, hydrothermal activity with temperatures exceeding 150°C have been found to be highly correlated to regional heat flow when that flow is in excess of 80 mW/m^2 (Blackwell et al. 2000 [DIRS 183582], Section 2.3).
>
> Most extensional geothermal systems in the U.S. appear to circulate to minimum depths of 4 to 6 km (Blackwell et al. 2000 [DIRS 183582], Section 3.5).

J6.1.1 Qualification Method

The methods of qualification for intended use of the data from the report by Blackwell et al. (2000 [DIRS 183582]) are the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5) and the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using these methods is that they were the most suitable considering the data, their existing documentation, and intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the evaluation of the data corroboration and technical assessment were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

- Extent and reliability of corroborating data or confirmatory results (#10).

J6.1.2 Technical Assessment

Extent to Which the Data Demonstrate the Properties of Interest—The publication describes a project focused on geothermal site-specific heat flow and thermal gradient data in the western United States. It included constructing a database of geothermal site-specific thermal gradient, heat flow, and thermal conductivity results from over 5,300 individual exploration wells. The database was assembled over a period of three years by compiling extensive temperature gradient and heat flow exploration data from the active geothermal system exploration of the 1970s and 1980s. The publication includes synthesis of the data, description of the database, as well as examples of the database applications. The data used for FEP 1.2.06.00.0A (Hydrothermal Activity) were obtained from Section 2.3 of the source (Blackwell et al. 2000 [DIRS 183582]), which discusses a modeling study that used heat flow and gradient from the database and then applied fault data to model an idealized, generic Basin and Range geothermal system as an example of extensional geothermal systems.

Qualification of Personnel or Organizations Generating the Data—The project described in the publication extended the earlier geothermal resource evaluations, which were documented in several publications presented in the peer-reviewed scientific journals. The primary author, D.D. Blackwell, is Hamilton Professor in the Earth Sciences Department of Southern Methodist University, specializing in the thermal state of the lithosphere and the geothermal resources in the United States. He has authored many scientific publications on this subject.

J6.1.3 Corroborating Data

The areas that are not geothermally active are the areas where the heat flow is low. From a regional perspective, the Yucca Mountain area is located adjacent to a large area of anomalously low heat flow (Flynn et al. 1996 [DIRS 112530], p. 92). Evaluation of geothermal characteristics within the Yucca Mountain area indicates that only low-temperature waters occur in and adjacent to Yucca Mountain and that the temperature gradient, and thus the heat flow, is low and below average. This information corroborates the data obtained from the report by Blackwell et al. (2000 [DIRS 183582]) that hydrothermal systems in the Basin and Range Province are found only in the areas where heat fluxes are high.

The hydrothermal water circulation depth is cited to be 4 to 5 km for the Whirlwind Valley hydrothermal system in Northern Nevada, in a region of high geothermal gradient (40°C/km to 60°C/km) (Wollenberg et al. 1975 [DIRS 107327], p. 7). This observation corroborates the minimum 4 to 6 km circulation depth for extensional hydrothermal systems given by Blackwell et al. (2000 [DIRS 183582], Section 3.5).

J6.1.4 Data Qualified for Intended Use

The technical assessment provides sufficient confidence that the data from Blackwell et al. (2000 [DIRS 183582]) presented above are adequate for intended use within FEP 1.2.06.00.0A

(Hydrothermal Activity). These data are qualified for intended use in the screening justification for this FEP.

J6.2 QUALIFICATION OF DATA FROM ROUSSEAU ET AL. 1997

Rousseau, J.P.; Loskot, C.L.; Thamir, F.; and Lu, N. 1997. *Results of Borehole Monitoring in the Unsaturated Zone Within the Main Drift Area of the Exploratory Studies Facility, Yucca Mountain, Nevada*. Milestone SPH22M3. Denver, Colorado: U.S. Geological Survey. ACC: MOL.19970626.0351. [DIRS 100178]

The data from this report to be qualified for intended use within this FEP include:

> In the Yucca Mountain area, the calculated heat flux within the TSw at boreholes NRG-7a, UZ-7a, and SD-12 is 37, 39, and 32 mW/m^2, respectively (Rousseau et al. 1997 [DIRS 100178], Section 5.2).

J6.2.1 Qualification Method

The method of qualification of the data listed above obtained from the report by Rousseau et al. (1997 [DIRS 100178]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that the data under consideration were evaluated previously and compared with the other relevant results. The data corroboration method was the most suitable considering the data, their existing documentation, and their intended use. Qualification process attributes used in the evaluation of the data corroboration and in technical assessment were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

- Extent and quality of corroborating data or confirmatory testing results (#10).

J6.2.2 Corroborating Data

The average of the data under consideration is 36 mW/m^2, with a standard deviation of 3.6 mW/m^2. The calculated heat flow data from Rousseau et al. (1997 [DIRS 100178]) are relevant to evaluating the potential for non-magmatic hydrothermal activity in the Yucca Mountain region and demonstrate the property of interest.

The report by Sass et al. (1988 [DIRS 100644]) provides data that are comparable with the heat flux data presented by Rousseau et al. (1997 [DIRS 100178]). Heat flux measurements are reported in Tables 5 and 6 of Sass et al. (1988 [DIRS 100644]). Of the measurements presented in these tables, the values from boreholes USW G-1, USW G-2, USW G-4, USW H-1, USW H-3, USW-H-4, USW H-5, UE25a4, UE25a5, UE25a6, UE25a7, UE25a1b1H, UZ-1, WT-2, WT-4, WT-6, WT-16, and WT-18 are in the vicinity of the boreholes (BSC 2007 [DIRS 182926]) used by Rousseau et al. (1997 [DIRS 100178]) to estimate heat flux. Note that in *IED Subsurface Facilities Geological Data* (BSC 2007 [DIRS 182926]), borehole designations beginning with "USW" and "UE25" have been abbreviated (e.g., "USW G-1" is

"G-1" and "UE25a4" is "A-4"). Borehole "UE25a1b1H" is shown as two adjacent boreholes, "A-1" and "B-1." Finally, borehole "WT-16" is not shown in the subsurface facilities document (BSC 2007 [DIRS 182926]), but can be seen to be in the general area presented in Figure 2 of Sass et al. (1988 [DIRS 100644]). The average and standard deviation of the UZ heat flux measurements from these boreholes given in Tables 5 and 6 of Sass et al. (1988 [DIRS 100644]) are 38 and 6.1 mW/m^2, respectively. Note that for boreholes with multiple heat flux measurements, the average value was used to determine the average and standard deviation over these boreholes. Thus, the mean of the Sass et al. (1988 [DIRS 100644]) heat fluxes lies within one standard deviation of the mean of the Rousseau et al. (1997 [DIRS 100178]) values (average of 36 mW/m^2 and a standard deviation of 3.6 mW/m^2). The heat flow data from Sass et al. (1988 [DIRS 100644]) have also been presented in the peer-reviewed journal article by Fridrich et al. (1994 [DIRS 100575], Section 9.2 and Figure 7). This favorable comparison indicates the reliability of the heat flux data from Rousseau et al. (1997 [DIRS 100178]).

J6.2.3 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the properties of interest and the existence of corroborating data, the data from Rousseau et al. (1997 [DIRS 100178]) are adequate for intended use within FEP 1.2.06.00.0A (Hydrothermal Activity). Based on the evaluation of corroborating data, the data meet qualification criteria outlined above and can be considered qualified for intended use within this FEP.

J6.3 QUALIFICATION OF DATA FROM WILSON ET AL. 2003

Wilson, N.S.F.; Cline, J.S.; and Amelin, Y.V. 2003. "Origin, Timing, and Temperature of Secondary Calcite–Silica Mineral Formation at Yucca Mountain, Nevada." *Geochimica et Cosmochimica Acta, 67,* (6), 1145-1176. New York, New York: Pergamon. [DIRS 163589].

The data from this journal article to be qualified for intended use within this FEP include:

> Studies of secondary minerals at Yucca Mountain using petrography, fluid-inclusion thermometry, and uranium-lead dating indicate that unsaturated-zone temperatures have remained close to the current ambient values over the past 2 to 5 Ma (Wilson et al. 2003 [DIRS 163589], Section 8).
>
> The unsaturated-zone secondary minerals were interpreted to have been deposited from downward percolating meteoric water and not the result of upwelling groundwaters (Wilson et al. 2003 [DIRS 163589], Sections 7.3 and 8).

J6.3.1 Qualification Method

The methods of qualification for intended use of the data obtained from the scientific paper by Wilson et al. (2003 [DIRS 163589]) listed above are the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2) and the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using these methods is that they were the most suitable considering the data, their existing documentation, their intended use, and availability of corroborating data. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the

qualification of these data were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviews of the data and their results (#8).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J6.3.2 Corroborating Data

These data are corroborated by an independent study by Bish and Aronson (1993 [DIRS 100006]). They correlated temperatures of formation of illite–smectite (from the saturated zone) and ages from K/Ar dating to conclude that no significant hydrothermal alteration has occurred since 10.7 Ma. These are independent data supporting the conclusion of Wilson et al. (2003 [DIRS 163589]). Additional corroborating data are presented by Whelan et al. (2002 [DIRS 160442]). The evaluation criterion is that the corroborating data set confirms that no significant hydrothermal alteration has occurred since 10.7 Ma. The independent study by Bish and Aronson (1993 [DIRS 100006]) supports an even longer period of constant temperature in the UZ at Yucca Mountain; thus the data from Wilson et al. (2003 [DIRS 163589]) are further corroborated.

J6.3.3 Technical Assessment

Extent to Which the Data Demonstrate the Properties of Interest—The property of interest is the long-term stability of the temperature regime at Yucca Mountain. Studies of secondary minerals at Yucca Mountain using petrography, fluid–inclusion microthermometry, and U–Pb dating indicate that temperatures have remained close to the current ambient values over the past two to five million years (Wilson et al. 2003 [DIRS 163589], Section 8). This is demonstrated by the relation between the temperatures (inferred from the composition of fluid inclusions) and the age of the inclusions, inferred from the U–Pb isotope dating. The study reported in the publication by Wilson et al. (2003 [DIRS 163589]) included the temperature regime for the formation of the secondary calcite–silica minerals in primary and secondary porosity of the host Miocene tuffs at Yucca Mountain and is, therefore, relevant to the properties of interest.

Prior Peer or Other Professional Reviews of the Data and their Results—Wilson et al. (2003 [DIRS 163589]) published their experimental results in the scientific journal *Geochimica et Cosmochimica Acta*. Published for over 100 years, *Geochimica et Cosmochimica Acta* is a professional scientific research journal for geochemistry and cosmochemistry. It is sponsored by The Geochemical Society and The Meteoritical Society and is published by Elsevier Science Ltd. Contributions to the journal are evaluated for scientific merit by thorough professional review. Peer review is an essential and integral aspect of *Geochimica et Cosmochimica Acta*. The fundamental role of the reviewer is to advise the Associate Editor and the Executive Editor on the technical merit, or lack thereof, of a manuscript submitted for publication. The Associate Editor writes a report summarizing reviewer opinion, presenting his/her overall evaluation based on his/her own reading of the manuscript and the advice of the reviewers. The peer review

process and the reputation of the journal ensure that the paper received adequate peer review. The journal typically requires three external reviews; Wilson et al. (2003 [DIRS 163589], p. 1,171) acknowledge input from seven reviewers.

J6.3.4 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the properties of interest, the existence of corroborating data, and the data review, the data from Wilson et al. (2003 [DIRS 163589]) are adequate for the intended use within FEP 1.2.06.00.0A (Hydrothermal Activity). These data are qualified for intended use in the screening justification for this FEP.

J7. FEP 1.2.07.01.0A – EROSION/DENUDATION

This FEP uses data from the following report as direct input:

Stuckless, J.S. and Levich, R.A., eds. 2007. *The Geology and Climatology of Yucca Mountain and Vicinity, Southern Nevada and California.* Memoir 199. Boulder, Colorado: Geological Society of America. TIC: 259378. [DIRS 181507]

This FEP uses data from the following report as direct input:

> Using a ^{10}Be cosmogenic dating technique, the calculated maximum possible erosion rates for bedrock outcrops at Yucca Mountain range from 0.4 to 2.7 cm/10,000 years (Stuckless and Levich 2007 [DIRS 181507], p. 83).
>
> The long-term rates of erosion of unconsolidated material from Yucca Mountain hillslopes were calculated to be 0.2 to 6 cm/10,000 years using the rock varnish cation ratio and the in situ cosmogenic ^{36}Cl dating methods (Stuckless and Levich 2007 [DIRS 181507], p. 84).

J7.1. QUALIFICATION METHOD

The methods of qualification of the data from Stuckless and Levich (2007 [DIRS 181507]) are the Corroborating Data and Technical Assessment methods (SCI-PRO-001, Attachment 3, Methods 2 and 5). The rationale for using both methods is that the conditions for the use of corroborating data are met, and the approaches for technical assessment also are applicable. The technical assessment included determination that confidence in the data acquisition or development was warranted and confirmation that the data had been used in similar applications. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior uses of the data and associated verification processes (# 7).
- Extent and reliability of the documentation associated with the data (#9).

J7.2. CORROBORATING DATA

The estimated maximum rate of erosion on ridge crests, outcrops, and hillslopes over 10,000 years was used in an order-of-magnitude manner to evaluate the potential for erosional processes to breach the geologic repository. The chapter cited within the reference, *Geology of the Yucca Mountain Site Area, Southwestern Nevada*, was authored by W. R. Keefer, J. W. Whitney, and D. C. Buesch (Stuckless and Levich (2007 [DIRS 181507], pp. 53 to 103). *Yucca Mountain Site Description* (BSC 2004 [DIRS 169734], Section 3.4.6) provides a summary description of the erosion processes occurring at Yucca Mountain during Quaternary time. Some of the data reported in that reference are the same as those in the publication by Stuckless and Levich (2007

[DIRS 181507]). Erosion rates were examined on hillslopes and bedrock outcrops on ridge crests in the Yucca Mountain site area. Initially, the surface exposure age of hillslope boulder deposits was calculated using the rock-varnish, cation-ratio dating method (Harrington and Whitney 1987 [DIRS 106095], pp. 967 to 970). Subsequently, cosmogenic ^{10}Be was also used to determine vertical erosion rates on bedrock outcrops on ridge crests of Yucca Mountain. From ^{10}Be measurements, tuff bedrock erosion rates were less than 4 cm per 10,000 years, while rates of erosion for hillslope coluvium were approximately 5 cm per 10,000 years (Gosse et al. 1996 [DIRS 170725]).

Analyses of ^{10}Be concentrations in quartz separates from tuffaceous bedrock exposed on Antler Ridge and the adjacent ridge to the south, on the east flank of Yucca Mountain, indicate a maximum possible erosion rate of bedrock to range from 0.4 to 2.7 cm per 10,000 years (Stuckless and Levich 2007 [DIRS 181507], p. 83). These values are compared in the report with the rock erosion rates measured in Australia and on granite landforms in Alabama Hills in California (Stuckless and Levich 2007 [DIRS 181507], p. 83) and the measured values agree well with the results of those other studies. The long-term erosion rates for Yucca Mountain hillslopes were found to be on the order of 2 cm per 10,000 years and are comparable with the high end of bedrock erosion rates (Stuckless and Levich 2007 [DIRS 181507], p. 84).

J7.3. TECHNICAL ASSESSMENT

Data Demonstrate the Properties of Interest—This report provides a detailed summary of bedrock and hillslope erosion rates for Yucca Mountain using a variety of methods.

Extent and Reliability of Documentation—This report thoroughly documents the ranges of bedrock and hillslope erosion rates for Yucca Mountain using a variety of methods. The report was published as a special Memoir (#199) by United States Geological Survey (USGS), representing one of the world's leading organizations in geological research.

Data Have Been Used in Similar Applications—Some of these data were previously used (YMP 1993 [DIRS 100520], Section 3.4) in other analyses and models supporting performance assessment for the Yucca Mountain repository (BSC 2004 [DIRS 169734], Section 3.4.6.2).

J7.4. DATA QUALIFIED FOR INTENDED USE

The data from Stuckless and Levich (2007 [DIRS 181507]) are appropriate for the intended use within FEP 1.2.07.01.0A (Erosion/Denudation). Based on the existence of corroborating data, the extent to which the data demonstrate the properties of interest, the extent and reliability of the documentation, and previous uses of similar data in similar applications, the erosion rate data can be considered qualified for intended use within this FEP.

J8. FEP 1.2.08.00.0A – DIAGENESIS

Diagenesis is an ongoing process of chemical and physical changes to sediments undergoing compaction, cementation, and burial. This FEP uses data from the following sources as direct input:

"Early Diagenesis in Continental Eolian Deposits" (Krystinik 1990 [DIRS 135295])

Caliche: Origin, Classification, Morphology and Uses (Reeves 1976 [DIRS 104303])

Impact of Time and Climate on Quaternary Soils in the Yucca Mountain Area of the Nevada Test Site (Taylor 1986 [DIRS 102864])

Factors Limiting Microbial Growth and Activity at a Proposed High-Level Nuclear Repository, Yucca Mountain, Nevada (Kieft et al. 1997 [DIRS 100767])

Secondary Mineral Deposits and Evidence of Past Seismicity and Heating of the Proposed Repository Horizon at Yucca Mountain, Nevada (Whelan 2004 [DIRS 170697]).

J8.1 QUALIFICATION OF DATA FROM KRYSTINIK 1990

Krystinik, L.F. 1990. "Early Diagenesis in Continental Eolian Deposits." Chapter 8 of *Modern and Ancient Eolian Deposits: Petroleum Exploration and Production*. Fryberger, S.G.; Krystinik, L.F.; and Schenk, C.J., eds. Denver, Colorado: Society of Economic Paleontologists and Mineralogists, Rocky Mountain Section. TIC: 247781. [DIRS 135295]

The data to be qualified within this FEP include:

> Compaction may reduce eolian sediments by as much as 20% to 30% (Krystinik 1990 [DIRS 135295], p. 8-2), but after this initial stage, compaction does not become an important factor in diagenesis until the onset of grain deformation and pressure solution during deeper burial diagenesis (Krystinik 1990 [DIRS 135295], p. 8-3).

J8.1.1 Qualification Method

The method of qualification for intended use of the data obtained from the scientific paper by Krystinik (1990 [DIRS 135295]) listed above is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, availability of corroborating data, their existing documentation, and their intended use. Qualification process attributes used in the qualification of these data were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J8.1.2 Corroborating Data

The two primary mechanisms for early and shallow diagenetic changes are related to compactions and cementation. Krystinik (1990 [DIRS 135295], pp. 8-3 and 8-4) indicates that early diagenesis "begins at or near the depositional interface and entails weathering, compaction, cementation and numerous allied physical, chemical and biochemical processes, at temperature below 50°C." Krystinik notes that "wind-laid sand can be deposited with up to 25% to 40% porosity and that early compaction reduces porosity by as much as 20% to 30%, depending upon sorting." Krystinik further states that "[b]eyond increasing capillarity, compaction does not generally become an important factor in diagenesis until the onset of grain deformation and pressure solution during deeper burial diagenesis." By minimizing compaction, then, the primary means of diagenesis becomes cementation processes.

By way of corroborating the role of compaction in early diagenesis, Palmer and Barton (1987 [DIRS 118483], pp. 32 and 39) compare similar, uncemented sands of increasing ages and burial depth with porosities. In the first 169 meters of burial, the porosity of the sand decreases from 47.2% to 35.6%, but from 169 m to 780 m, the compaction only decreased the porosity an additional 2%, for a total decrease of 13.6%. This corroborates Krystinik's assertion of an initial reduction of no more than a few percent, followed by minimal effects. The lack of compaction during initial burial is also corroborated by the Sclater-Christie compaction curve given by Baldwin and Butler (1985 [DIRS 167871], Figure 3). The curve shows that change in porosity during the first 300 m of burial is insignificant, but becomes increasingly more important at greater depths, with changes of up to 50% porosity relative to the initial porosities occurring at depths approaching 10 km. However, Baldwin and Butler also caution that sandstones show considerable scatter in solidity-depth values and indicate that ranges in values of 25% are common. As a "case-in-point," the work by Salem et al. (1998 [DIRS 167869], pp. 319 to 331) on cratonic sandstones indicates that sandstones undergoing burial between 1.5 and 2.5 km exhibited only a 19% total porosity loss due to compaction. The results of this work match well with the compaction curves of Baldwin and Butler for a 1 to 2 km burial depth, and further corroborates Krystinik's assertion that compaction plays only a minor role during the early stages of shallow burial and diagenesis.

J8.1.3 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the properties of interest and the existence of corroborating data, the data from Krystinik (1990 [DIRS 135295]) are adequate for intended use within FEP 1.2.08.00.0A (Diagenesis). These data are qualified for intended use in the screening justification for this FEP.

J8.2 QUALIFICATION OF DATA FROM REEVES 1976

Reeves, C.C. 1976. *Caliche: Origin, Classification, Morphology and Uses*. Lubbock, Texas: Estacado Books. TIC: 245928. [DIRS 104303]

The data to be qualified within this FEP include:

> The net effects of shallow diagenesis and associated cementation on infiltration in an arid environment are to stabilize the surface environment, and decrease the net vertical infiltration rate (Reeves 1976 [DIRS 104303], p. 110).

J8.2.1 Qualification Method

The method of qualification for intended use of the data obtained from the book by Reeves (1976 [DIRS 104303]) listed above is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use, as well as availability of corroborating data. Qualification process attributes used in the qualification of these data were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J8.2.2 Corroborating Data

With regard to the role of cementation in diagenesis and its effects, Reeves (1976 [DIRS 104303], p. 110) indicates that the net effects of shallow diagenesis and associated cementation is to decrease the net vertical infiltration rate and cites multiple studies to support that assertion. This net reduction in infiltration is corroborated by Lattman (1983 [DIRS 167815], pp. 107 to 108) who states, "[t]he formation of caliche inhibits infiltration into a topographic surface. The degree of this inhibition is a function of density and induration of the caliche. Petrocalcic horizons, laminar layers, and case-hardened layers cause the greatest inhibition." It is also corroborated by Arakel (1996 [DIRS 167623], p. 223), who refers to progressive plugging of initial porosity/permeability zones. It should be pointed out that while this holds true for the carbonates, Taylor (1986 [DIRS 102864]) indicates that in the YMP soils studied, in the absence of effective precipitation or drainage to remove newly dissolved silica, it is precipitated elsewhere within the calcrete horizon, or $CaCO_3$ preferentially precipitates after opaline silica bonds adjacent soil grains. Taylor notes that this process may occur without necessarily plugging intervening pores spaces.

J8.2.3 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the properties of interest and the existence of corroborating data, the data from the book by Reeves (1976 [DIRS 104303]) are appropriate for

intended use within FEP 1.2.08.00.0A (Diagenesis). These data are qualified for use in the screening justification for this FEP.

J8.3 QUALIFICATION OF DATA FROM TAYLOR 1986

Taylor, E.M. 1986. *Impact of Time and Climate on Quaternary Soils in the Yucca Mountain Area of the Nevada Test Site*. Master's thesis. Boulder, Colorado: University of Colorado. TIC: 218287. [DIRS 102864]

The technical information to be justified within this FEP include:

> SiO_2 cementation is not dependent on climatic conditions, but cementation does exhibit distinctive trends that correspond with the ages of the surficial deposits (Taylor 1986 [DIRS 102864], Chapter 5).
>
> Accumulation rates are attributable to several climatic scenarios, but climate change was insufficient to significantly decrease the rate of accumulations (Taylor 1986 [DIRS 102864], Chapter 5).
>
> Cementation by opaline SiO_2 is common in the Yucca Mountain study area, and opaline SiO_2 accumulation in the soils is favored over that of $CaCO_3$ (Taylor 1986 [DIRS 102864], Figure 9 and pp. 31 to 33).

J8.3.1 Qualification Method

The method of qualification for intended use of the data obtained from the thesis by Taylor (1986 [DIRS 102864]) listed above is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. Qualification process attributes used in the qualification of these data were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

Data evaluation criteria were based on consideration of these attributes and arriving at an affirmative conclusion that a given attribute is met by the data under consideration.

J8.3.2 Corroborating Data

Taylor (1986 [DIRS 102864], Chapter 5) indicates silts that formed in alluvium and eolian fines of Holocene to early Pleistocene or late Pliocene age near Yucca Mountain are characterized by distinctive trends in the accumulation of secondary clay, $CaCO_3$, and opaline SiO_2 that correspond with the ages of the surficial deposits, although there is no macro- or micromorphological evidence that suggests that silica cementation occurred under climatic conditions cooler and wetter than those of the present climate. Taylor also states that

accumulation rates of these materials during the Holocene can be attributed to several possible climatic scenarios associated with the Holocene-Pleistocene climate change, but suggests that precipitation has not been a limiting factor, and that climatic change was not sufficient to significantly decrease rate of accumulation. Taylor also suggests that the climatic change was the result of decreases in temperature rather than precipitation. Modeling results discussed by Taylor suggest that increased precipitation in the future may translocate $CaCO_3$ accumulations to greater depths, where precipitation is greater. Taylor also suggests that the cementation process, particularly for $CaCO_3$, is reversible, and that the material can be redissolved and moved deeper into the soil profile.

The dependence of the accumulation depth of $CaCO_3$, and the dependence of other diagenetic effects related to chemical changes, is corroborated by several sources. Eghbal and Southard (1993 [DIRS 167625], p. 1049) suggest that, in the Mojave Desert, development of carbonate-free argillic horizons probably occurred during pluvial periods, whereas calcification occurred during drier periods. Silicification appears to have been contemporaneous with both clay illuviation and calcification and, thus, may be related to pedochemical conditions rather than to climate. This corroborates the results by Taylor (1986 [DIRS 102864], Chapter 5) discussed above, and for a similar arid setting. Eghbal and Southard further unequivocally state that soils in arid regions are often polygenetically related to climatic variations. This trend for calcification is also corroborated in the abstract by Lattman (1972 [DIRS 167813]) in the statement "[i]t is suggested that extensive calcrete layers in southern Nevada formed during and immediately following the onset of pluvial periods which were times of fan aggradation. They were generally destroyed during the interpluvial, which were times of fan stability or degradation." This statement also tends to suggest that calcification effects may be reversible, whereas silicification may be ongoing regardless of the climate state.

Further corroboration is gained from Chadwick et al. (1995 [DIRS 167626]), who document changes in soil profiles along a transect that reflect cooler and wetter conditions due to elevation changes. However, these serve as a surrogate for change in climate conditions. In particular, they observed that climatic extremes drive pedogenic processes that leave polygenetic imprints on soils of Pleistocene age. In particular, soils that are now dominated by opaline silica, carbonate, and smectite contain evidence of earlier, more acidic, chemical environments conducive to dissolution of primary carbonate and formation of kaolinite. During interglacial times (i.e., drier and warmer), Chadwick et al. attribute the changes to more eolian activity and less effective moisture combining to decrease the depth of leaching, increase base cations, and modify the soil chemical environment in relict paleosols. This trend toward increased calcification during pluvial times is corroborated in the accumulation rates noted in the abstract by Machette (1982 [DIRS 167814]), who indicates that soils <25,000 years old have accumulation rates 2 to 3 times higher than older soils. This observation is attributed to "less effective precipitation and vegetation cover in Holocene time," which is due in large part to a drier climate state. The increased accumulation rates of $CaCO_3$ are also noted by Eghbal and Southard (1993 [DIRS 167624], pp.170 to 171).

Taylor (1986 [DIRS 102864], Figure 9) indicates that the accumulation rate of $CaCO_3$, while occurring, is significantly less than that for SiO_2. This is reflected in statements indicating that carbonate is primarily derived from airborne dust and the opaline SiO_2 from in-place weathering of the parent material and that the cementation by opaline SiO_2 is common in the study area and

that opaline SiO_2 accumulation in the soils is favored over that of $CaCO_3$. Taylor also indicates that SiO_2 cementation is common in the study area, with $CaCO_3$ as an accessory cement. The direct input from Taylor indicating the predominance of SiO_2 over carbonate in the soil cements is corroborated by Lattman (1973 [DIRS 129305], p. 3015). In studies near Las Vegas, Lattman observed that calcium carbonate cementation is not necessarily a significant cementation process in rhyolitic tuffs due to the lack of carbonate source materials. The above statements by Lattman and Taylor's observations of the predominance of SiO_2 cements mentioned above, is mutually corroborative with statements from Krystinik (1990 [DIRS 135295], p. 8-4) that cements other than carbonate may develop, particularly iron, silica, and aluminum. Yaalon (1967 [DIRS 167622], p. 1189) corroborates this by indicating that one of the controlling factors in diagenesis of eolian sands is the original content of $CaCO_3$. As a corroborative example from indirect input, the presence of cements other than carbonate in arid environments is proposed in a study by Salem et al. (1998 [DIRS 167869], pp. 319 to 331). In that particular study, the predominant cements stemming from the generally arid environment were iron and silica.

J8.3.3 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the properties of interest and the existence of corroborating data, the data from the thesis by Taylor (1986 [DIRS 102864]) are considered qualified for intended use within FEP 1.2.08.00.0A (Diagenesis).

J8.4 QUALIFICATION OF DATA FROM KIEFT ET AL. 1997

Kieft, T.L.; Kovacik, W.P., Jr.; Ringelberg, D.B.; White, D.C.; Haldeman, D.L.; Amy, P.S.; and Hersman, L.E. 1997. "Factors Limiting Microbial Growth and Activity at a Proposed High-Level Nuclear Repository, Yucca Mountain, Nevada." *Applied and Environmental Microbiology, 63,* (8), 3128-3133. Washington, D.C.: American Society for Microbiology. TIC: 236444. [DIRS 100767]

The data to be qualified for intended use within this FEP include the following statements:

> Total counts (microscopic direct and plate) ranged from below limit of detection (3.2×10^4 cells per gram) to 2.3×10^5 cells per gram (Kieft et al. 1997 [DIRS 100767], p. 3,130).
>
> Phospholipid fatty acid (PLFA) concentrations were generally low, ranging from 0.1 to 3.7 pmol per gram (Kieft et al. 1997 [DIRS 100767], p. 3,130).

J8.4.1 Qualification Method

The method of qualification for intended use of the external data from Kieft et al. (1997 [DIRS 100767]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their intended use, as well as availability of corroborating data. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001.

Attributes specifically applicable to these data are:

- Extent and quality of corroborating data or confirmatory testing results (#10).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).

J8.4.2 Corroborating Data

The intended use of the data is to support the statement "Plate count, direct count, and phospholipid fatty acid (PLFA) data indicate a low abundance of microorganisms in Yucca Mountain tuff" (Kieft et al. 1997 [DIRS 100767], p. 3,130) for use in FEP 1.2.08.00.0A. The conclusion statement by Kieft et al. (1997 [DIRS 100767]), "[p]late count, direct count, and PLFA data indicate a low abundance of microorganisms in Yucca Mountain tuff", is supported by data represented in Figures 2 and 3 within the reference. Using a variety of methods, plate count, direct count, and PLFA, the results reported within this source mutually corroborate the statement the microorganisms are in low abundance in Yucca Mountain tuff. Furthermore, these results are consistent with findings from additional studies by Haldeman and Amy (1993 [DIRS 145228]) and Horn (2004 [DIRS 171058]). Kieft et al. report that the range of microorganisms found is on the order of 10^4 to 10^5 cells per gram tuff. Horn et al. (2004 [DIRS 171058]) report values of values of 4×10^4 and 6×10^4 cells per gram of dry rock from an ESF rock core. These results are consistent with previous findings of $<1 \times 10^1$ to 2.4×10^5 colony forming units per gram of dry rock for unsaturated tuff from Rainier Mesa tunnel systems on the Nevada Test Site (Haldeman and Amy 1993 [DIRS 145228]). These data represent an overall low microorganism total count and are adequate and accurate for the intended use within this FEP.

J8.4.3 Data Qualified for Intended Use

Based upon the discussion provided above and the strong corroborative results from additional studies, the data described above support the statement of low abundance of microorganism in Yucca Mountain tuff and are adequate for use within FEP 1.2.08.00.0A (Diagenesis). The data are qualified for use in the screening justification for this FEP.

J8.5 QUALIFICATION OF DATA FROM WHELAN 2004

Whelan, J.F. 2004. *Secondary Mineral Deposits and Evidence of Past Seismicity and Heating of the Proposed Repository Horizon at Yucca Mountain, Nevada.* Water-Resources Investigations Report 03-4321. Reston, Virginia: U.S. Geological Survey. ACC: MOL.20040902.0236. [DIRS 170697]

The data to be qualified for intended use within this FEP include the following statements:

> Calcite and silica (quartz, chalcedony, and opal) are found in some open fractures and lithophysal cavities in the Topopah Spring and Tiva Canyon Tuffs in the UZ. Studies indicate that secondary minerals form in the UZ from meteoric waters percolating along fractures to the water table. Therefore, there is a link between pedogenic deposition on

the overlying soil, infiltration of meteoric water, and secondary mineral deposition in the UZ. Deposits of secondary minerals are sparsely and heterogeneously distributed on less than 10% of potential fracture and cavity depositional sites (Whelan 2004 [DIRS 170697], p. 3).

J8.5.1 Qualification Method

The method of qualification for the data from Whelan (2004 [DIRS 170697]) listed above is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it is the most appropriate considering the extent of available documentation. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Process attributes used in the qualification of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).

- The extent and reliability of the documentation associated with the data (#9).

J8.5.2 Technical Assessment

The statement under consideration concerns the observation and characterization of secondary mineral deposits in lithophysal cavities along some fracture surfaces within the ESF and ECRB Cross Drift. Secondary mineral studies have been conducted by the USGS since 1995 using a variety of visual and isotopic techniques. The characterization of the secondary calcite and silica deposits from ESF and ECRB tunnel samples is documented in numerous publications (e.g., Whelan et al. 1994 [DIRS 100091]; Whelan and Moscati 1998 [DIRS 109179]; Paces et al. 2001 [DIRS 156507]; Whelan et al. 2002 [DIRS 160442]), in detailed labeled photomicrographs of petrographic thin sections (see, for example, Figure 8 of Whelan 2004 [DIRS 170697]), and by an extensive database of $\delta^{18}O$ and $\delta^{13}C$ analyses (e.g., DTN: GS020908315215.004 [DIRS 164847]), U-series age-dates (e.g., DTN: GS021208315215.009 [DIRS 164750]), and fluid-inclusion homogenization temperatures (e.g., DTN: GS020908315215.003 [DIRS 164846]). The isotopic analyses in particular support the pedogenic origin of the calcite, and its deposition under temperatures generally less than 60°C over at least the past ten million years. The intended use of the data is to support the statement "A principal effect of deeper diagenesis at Yucca Mountain is the infilling and coating of open fractures and lithophysal cavities by calcite and silica (Whelan 2004 [DIRS 170697], p. 3)" within FEP 1.2.08.00.0A (Diagenesis). In this manner the data demonstrates the properties of interest that calcite and silica are present in the unsaturated zone at Yucca Mountain as diagenetic features that have been established over millions of years.

J8.5.3 Data Qualified for Intended Use

The technical assessment of these data provides sufficient confidence that these data are adequate and are considered qualified for intended use within FEP 1.2.08.00.0A (Diagenesis).

J9. FEP 1.2.09.02.0A – LARGE SCALE DISSOLUTION

This FEP uses data and technical information from the following publication as direct input:

Freeze, R.A. and Cherry, J.A. 1979. *Groundwater.* Englewood Cliffs, New Jersey: Prentice-Hall. TIC: 217571. [DIRS 101173]

The data and technical information to be qualified for use within this FEP include:

> In water at 1 atm pressure, 25°C, and pH 7, mineral solubilities are 12 mg/L for quartz, 90 to 500 mg/L for carbonates (depending on CO_2 partial pressure), and 360,000 mg/L for halite (Freeze and Cherry 1979 [DIRS 101173], p. 106).
>
> Extensive carbonate dissolution cavities are not expected to develop because such dissolution is not typically observed in carbonates at great depths below the water table (Freeze and Cherry 1979 [DIRS 101173], pp. 514 to 515).

J9.1 QUALIFICATION METHOD

The method of qualification for the data from Freeze and Cherry (1979 [DIRS 101173]) listed above is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment included determination that confidence in the data acquisition or development was warranted. Process attributes used in the qualification of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).
- Qualification of personnel generating the data (#1).

J9.2 TECHNICAL ASSESSMENT

The Extent to Which the Data Demonstrate the Properties of Interest—The specific solubility values used in the FEP are those for carbonate, halite, and quartz. The solubility values were used in a qualitative sense to demonstrate that the predominate Yucca Mountain rock units are relatively insoluble; solubility values were not used quantitatively in a model or calculation. Therefore, use of solubility data from Freeze and Cherry (1979 [DIRS 101173]) in the FEP to support arguments concerning the large-scale dissolution of YMP rock units is technically adequate and appropriate.

Qualification of Personnel or Organizations Generating the Data—R. Allan Freeze is former Professor and Director in the Geological Engineering Program at the University of British Columbia in Vancouver, Canada. He is the coauthor of *Groundwater* (1979) and *Groundwater Contamination: Optimal Capture and Containment* (1993), and the coeditor of *Physical Hydrogeology* (1983). John A. Cherry has been a professor at the University of Waterloo since 1971. He has a Ph.D. in Hydrogeology and is coauthor of the highly acclaimed textbook on

hydrogeology, *Groundwater*, published by Prentice-Hall. The textbook (Freeze and Cherry 1979 [DIRS 101173]) underwent extensive reviews from professional peers and was trial tested by many graduate and undergraduate students before publication.

The publication was designed as a text in introductory groundwater courses normally taught in undergraduate geology, geological engineering, or civil engineering curricula and has been used extensively by university students for almost thirty years. The authors recognized the need to include material beyond the normal geologic and hydraulic aspects of groundwater studies, so they included three major chapters primarily chemical in emphasis. Data used to support FEP 1.2.09.02.0A are from one of the three Freeze and Cherry (1979 [DIRS 101173]) chapters, "Chemical Properties and Principles."

J9.3 DATA QUALIFIED FOR INTENDED USE

Based on the assessment made above, solubility data and information on formation of cavities from Freeze and Cherry (1979 [DIRS 101173]) are appropriate for intended use within FEP 1.2.09.02.0A (Large Scale Dissolution). These data are qualified for use in the screening justification for this FEP.

J10. FEP 1.2.10.01.0A – HYDROLOGIC RESPONSE TO SEISMIC ACTIVITY

This FEP uses data from the following report as direct input:

Ground Water at Yucca Mountain, How High Can It Rise? Final Report of the Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain (National Research Council 1992 [DIRS 105162]).

J10.1 QUALIFICATION OF DATA FROM NATIONAL RESEARCH COUNCIL 1992

National Research Council 1992. *Ground Water at Yucca Mountain, How High Can It Rise? Final Report of the Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain.* Washington, D.C.: National Academy Press. TIC: 204931. [DIRS 105162]

The data from the National Research Council report to be qualified for intended use within this FEP concern the predicted changes in the water table elevation in response to seismic activity. The intended use of the data overlaps with FEPs 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) and 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults) and includes the following statement:

> Results from the regional stress model approach indicated a maximum water table rise of 50 m (National Research Council 1992 [DIRS 105162], Chapter 5, p. 116).

J10.2 Qualification Method

The same data obtained from the same reference and used in an analogous context were qualified for intended use in FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock). The data were qualified for intended use using the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5) with the consideration of the qualifications of personnel or organizations generating the data and the extent to which the data demonstrate the properties of interest. The rationale for selecting the technical assessment data qualification method and the attributes of the data qualification process used for FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) are also applicable to qualifying the data from the National Research Council report (National Research Council 1992 [DIRS 105162]) for the intended use in FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

J10.3 Data Qualified for Intended Use

Based on the evidence provided for FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) and the intended use of the data in FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity), the data from the National Research Council (1992 [DIRS 105162]) are appropriate and are qualified for intended use in the screening justification for FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

J11. FEP 1.2.10.02.0A – HYDROLOGIC RESPONSE TO IGNEOUS ACTIVITY

This FEP uses data from the following report as direct input:

Valentine, G.A.; WoldeGabriel, G.; Rosenberg, N.D.; Carter Krogh, K.E.; Crowe, B.M.; Stauffer, P.; Auer, L.H.; Gable, C.W.; Goff, F.; Warren, R.; and Perry, F.V. 1998. "Physical Processes of Magmatism and Effects on the Potential Repository: Synthesis of Technical Work Through Fiscal Year 1995." Chapter 5 of *Volcanism Studies: Final Report for the Yucca Mountain Project.* Perry, F.V.; Crowe, B.M.; Valentine, G.A.; and Bowker, L.M., eds. LA-13478. Los Alamos, New Mexico: Los Alamos National Laboratory. TIC: 247225. [DIRS 119132]

The data to be qualified for intended use within this FEP include:

> Mineral alterations around igneous intrusions at natural analogue sites show that alteration is limited to a zone that extends less than 10 m away from the intrusion/host rock contact (Valentine et al. 1998 [DIRS 119132], p. 5-74).

These data are identical to the data used in FEP 1.2.04.02.0A (Igneous Activity Changes Rock Properties) and the intended use of these data is the same. Therefore, these data are appropriate for intended use within FEP 1.2.10.02.0A (Hydrologic Response to Igneous Activity). Based on the discussion and the qualification presented in this appendix for FEP 1.2.04.02.0A (Igneous Activity Changes Rock Properties), the data can be considered qualified.

J12. FEP 1.3.04.00.0A – PERIGLACIAL EFFECTS

This FEP uses data from the following report as direct input:

Thompson, R.S.; Anderson, K.H.; and Bartlein, P.J. 1999. *Quantitative Paleoclimatic Reconstructions from Late Pleistocene Plant Macrofossils of the Yucca Mountain Region.* Open-File Report 99-338. Denver, Colorado: U.S. Geological Survey. ACC: MOL.19991015.0296. [DIRS 109470]

The data to be qualified for intended use within this FEP include:

> During the last glacial maximum, the mean annual temperature at Yucca Mountain exceeded 0°C (Thompson et al. 1999 [DIRS 109470], Figures 17 and 18).

J12.1. QUALIFICATION METHOD

The methods of qualification for intended use of the data from Thompson et al. (1999 [DIRS 109470]) are the Corroborating Data and Technical Assessment methods (SCI-PRO-001, Attachment 3, Methods 2 and 5). The rationale for using both methods is that the conditions for the use of corroborating data are met, and the approaches for technical assessment also are applicable. The technical assessment included determination that confidence in the data acquisition or development was warranted and confirmation that the data had been used in similar applications. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organization generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (# 1).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior uses of the data and associated verification processes (# 7).
- Extent and quality of corroborating data or confirmatory testing results (# 10).

J12.2. CORROBORATING DATA

The data on temperature during the last full glacial period in the report by Thompson et al. (1999 [DIRS 109470]) are corroborated by the data from the USGS Open-File Report 83-535 titled *Vegetation and Climates of the Last 45,000 Years in the Vicinity of the Nevada Test Site, South-Central Nevada* (Spaulding 1983 [DIRS 101623], p. 2, Tables 4 and 10), which also indicate the above-freezing annual average temperatures during the last full glaciation period.

J12.3. TECHNICAL ASSESSMENT

Data Were Collected by Qualified Individuals—Robert S. Thompson has been a research geologist at the USGS for over twenty years. Dr. Thompson's research focuses on the interactions between environmental and climatic changes through time, from the Pliocene to the present day and into the future. He leads the Climate Change, Land Use, and Environmental Sensitivity (CLUES) Project, which investigates modern relations between plant distributions and climate, provides quantitative paleoclimatic reconstructions from paleobotanical data, and employs arrays of paleoenvironmental data to assess the ability of climate models to simulate climates different from that of today. He has served in several leadership positions within the USGS, including: Team Chief Scientist for the Global Change and Climate History Team, Team Chief Scientist for the Central Region Earth Surface Process Team, acting Coordinator for the Earth Surface Dynamics program, and acting Regional Geologist in the Central Region.

Data Demonstrate the Properties of Interest—Based on data from modern analogues, the report shows that the estimated mean annual temperature was between 7.9°C and 8.5°C at Yucca Mountain (for an elevation of 5,000 ft. (1,524 m)) during the last glacial maximum (Thompson et al. 1999 [DIRS 109470], Table 4). These data are used to predict that the annual average temperature during the coolest climate state over the next 10,000 years will be above freezing. These data are relevant with respect to the property of interest.

Data Have Been Used in Similar Applications—The data were used in other analyses and models supporting performance assessment for the Yucca Mountain repository (BSC 2004 [DIRS 170002], pp. 6-34 and 6-47; BSC 2004 [DIRS 169734], Sections 6, 6.4.2.1, and 6.5.4, Tables 6-27 and 6-29).

J12.4. DATA QUALIFIED FOR INTENDED USE

The above discussion provides confidence that the data from the report by Thompson et al. (1999 [DIRS 109470]) are appropriate for intended use and are qualified for use in the screening argument for FEP 1.3.04.00.0A (Periglacial Effects).

J13. FEP 1.3.05.00.0A – GLACIAL AND ICE SHEET EFFECT

This FEP uses data from the following report as indirect input:

Thompson, R.S.; Anderson, K.H.; and Bartlein, P.J. 1999. *Quantitative Paleoclimatic Reconstructions from Late Pleistocene Plant Macrofossils of the Yucca Mountain Region.* Open-File Report 99-338. Denver, Colorado: U.S. Geological Survey. ACC: MOL.19991015.0296. [DIRS 109470]

The data to be qualified for intended use within this FEP include:

> During the last glacial maximum, the mean annual temperature at Yucca Mountain exceeded 0°C (Thompson et al. 1999 [DIRS 109470], Figures 17 and 18).

These data are identical to the data used in FEP 1.3.04.00.0A (Periglacial Effects) and are qualified for intended use within FEP 1.3.05.00.0A (Glacial and Ice Sheet Effect). See the section in this appendix that addresses qualification of data for FEP 1.3.04.00.0A (Periglacial Effects) for a complete discussion of the qualification.

J14. FEP 1.5.01.01.0A – METEORITE IMPACT

Data qualification for FEP 1.5.01.01.0A (Meteorite Impact) is presented in Appendix D.

This FEP uses data from the following publications and the report as direct inputs:

Grieve, R.A.F. and Robertson, P.B. 1984. "The Potential for the Disturbance of a Buried Nuclear Waste Vault by a Large-Scale Meteorite Impact." *Workshop on Transitional Processes Proceedings, held in Ottawa, 1982 November 4 and 5. AECL-7822,* 231-269. Pinawa, Manitoba, Canada: Whiteshell Nuclear Research Establishment. TIC: 227319. [DIRS 185030]

Grieve, R.F. 1987. "Terrestrial Impact Structures." *Annual Review of Earth and Planetary Sciences*, 15, 245-269. Palo Alto, California: Annual Reviews. TIC: 246788. [DIRS 135254]

Grieve, R.; Rupert, J.; and Therriault, A. 1995. "The Record of Terrestrial Impact Cratering." *GSA Today*, 5, (10), 194-196. Boulder, Colorado: Geological Society of America. TIC: 246688. [DIRS 135260]

Grieve, R.A.F. 1998. "Extraterrestrial Impacts on Earth: The Evidence and the Consequences." *Meteorites: Flux with Time and Impact Effects.* Grady, M.M.; Hutchinson, R.; McCall, G.J.H.; and Rothery, D.A., eds. Geological Society Special Publication No. 140. Pages 105-131. London, England: Geological Society. TIC: 254143. [DIRS 163385]

Hills, J.G. and Goda, P.M. 1993. "Fragmentation of Small Asteroids in the Atmosphere." *The Astronomical Journal, 105*, (3), 1114-1144. Woodbury, New York: American Institute of Physics. TIC: 246798. [DIRS 135281]

Wuschke, D.M.; Whitaker, H.H.; Goodwin, B.W.; and Rasmussen, L.R. 1995. *Assessment of the Long-Term Risk of a Meteorite Impact on Hypothetical Canadian Nuclear Fuel Waste Disposal Vault Deep in Plutonic Rock*. AECL-11014. Pinawa, Manitoba, Canada: Atomic Energy of Canada Limited, Whiteshell Laboratories. TIC: 221413. [DIRS 129326]

The publications listed above are sources of direct input data and technical information. The justification for the use of technical information as well as the methods of qualification, qualification process attributes, and criteria for the data are presented in Appendix D.

J15. FEP 1.5.01.02.0A – EXTRATERRESTRIAL EVENTS

This FEP uses data from the following journal article and the report as direct inputs:

Gamma and Neutrino Radiation Dose from Gamma Ray Bursts and Nearby Supernovae (Karam 2002 [DIRS 167872])

Terrestrial Paleoenvironmental Effects of a Late Quaternary-Age Supernova (Brakenridge 1981 [DIRS 167873]).

J15. QUALIFICATION OF DATA FROM KARAM 2002

Karam, P.A. 2002. "Gamma and Neutrino Radiation Dose from Gamma Ray Bursts and Nearby Supernovae." *Health Physics, 82,* (4), 491-499. Philadelphia, Pennsylvania: Lippincott Williams & Wilkins. TIC: 255918. [DIRS 167872]

The data to be qualified for intended use within this FEP include:

> 20 mm of rock thickness provides at least seven orders of magnitude reduction in the photon energy absorbed by the rocks (i.e., the absorbed dose) for the incident 20 keV photon radiation (Karam 2002 [DIRS 167872], Table 2).

J15.1.1 Qualification Method

The method of qualification for intended use of the data from Karam (2002 [DIRS 167872]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and reliability of the documentation associated with the data (#9).

J15.1.2 Technical Assessment

Qualifications of Personnel or Organizations Generating the Data—Dr. P. Andrew Karam is currently a Senior Health Physicist for MJW Corporation, Inc., a professional consulting firm specializing in radiological and health physics services for private industry and government agencies. He has also served as a faculty member for Rochester Institute of Technology and the University of Rochester in the departments of Applied Science and Technology, Biological

Sciences, Environmental Health, and Earth and Environmental Sciences. His experiences also include work as a Health Physicist at Ohio State University and as a Radiation Safety Officer at the University of Rochester. His military experience includes eight years in the U.S. Navy's Nuclear Power Program, including three years on an attack submarine as supervisor of the Reactor Laboratories Division.

Dr. P. Andrew Karam has over a quarter century of experience that spans the breadth of radiation safety in the workplace, in the environment, and in the military. An internationally recognized authority, Dr. Karam served on the Health Physics Society's Board of Directors, a National Academy of Sciences subcommittee on the effects of battlefield use of depleted uranium, and on a committee for the National Council of Radiation Protection and Measurements. He provides consulting services to the International Atomic Energy Agency on matters pertaining to radioactive materials security and national radiation safety regulation programs.

Dr. Karam has taught and published extensively on the effects of radiation exposure. He is the author of over 20 peer-reviewed papers (including the reference discussed here), three book chapters, and over 200 non-peer-reviewed technical presentations and publications. *Health Physics*, the journal in which this paper was published, is the premier supplier of cutting edge information about radiation safety for all radiation safety professionals, including health physicists, nuclear chemists, nuclear engineers, biomedical researchers and physicians. *Health Physics* reports on the latest findings in theoretical, applied, and practical disciplines of epidemiology and radiation effects, radiation biology, radioactive material transport, radiation medicine, and good radiation safety practice.

Extent to Which the Data Demonstrate the Properties of Interest—This paper provides a discussion of the frequency of supernovae and gamma ray bursts and quantifies the expected dose in the surface and subsurface. The paper clearly indicates that there is at least seven orders of magnitude reduction in dose within the top 20 mm of rock, suggesting that dose at the repository depth from such events would be negligible.

Extent and Reliability of the Documentation Associated with the Data—Base equations and assumed values are given. The discussions and conclusions are adequately documented and supporting citations are provided.

J15.1.3 Data Qualified for Intended Use

Based on the extensive experience and qualifications of the personnel generating the data, and the extent to which the data demonstrate the properties of interest, these data are considered both adequate and reliable. Therefore, based on the discussions above, these data are qualified for intended use within FEP 1.5.01.02.0A (Extraterrestrial Effects).

J15.2 QUALIFICATION OF DATA FROM BRAKENRIDGE 1981

Brakenridge, G.R. 1981. "Terrestrial Paleoenvironmental Effects of a Late Quaternary-Age Supernova." *Icarus, 46,* (1), 81-93. New York, New York: Academic Press. TIC: 255707. [DIRS 167873]

The data to be qualified for intended use within this FEP include:

> The postulated climatic and environmental effects of supernovae include ozone depletion for between two and six years, small but significant global cooling (from 0.4 K to 2 K), and an increased transfer of stratospheric nitrogen into tropospheric and fixed nitrogen on the Earth's surface (Brakenridge 1981 [DIRS 167873], p. 85).
>
> The estimated time of occurrence of Vela supernova occurred about 11,300 to 8,400 years ago (Brakenridge 1981 [DIRS 167873], p. 85).

J15.2.1 Qualification Method

The method of qualification for intended use of the data from the scientific journal article by Brakenridge (1981 [DIRS 167873]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and Quality of Corroborating Data (#10).

J15.2.2 Technical Assessment

Extent to Which the Data Demonstrate the Properties of Interest—The properties of interest demonstrated in the paper by Brackenridge (1981 [DIRS 167873]) are the ways in which a supernova comparable to the Vela event could affect the terrestrial environment, including global climate. The paper by Brakenridge discusses the potential effects of a late Quaternary-Age supernova on the terrestrial paleoenvironment. It discusses the frequency of gamma and X radiation incident upon the earth and discusses potential climate forcing mechanisms and proposes evidence that such events are recorded in paleosoil horizons. The paper indicates that over 120 radio-emitting galactic supernova remnants have been catalogued. Figure 1 of the paper provides a plot of the energy fluence (called the peak flux in the paper) and the timing of the initiating supernova event. At least 24 significant (i.e., greater than 500 erg/cm^2 = 0.5 J/m^2) peaks were observed for events occurring within the 15,000 years before present. Using a value of 120 events in the past 15,000 years suggests a rate of approximately one event per 100 years. The most significant of these peak fluxes was for the Vela supernova, which was calculated to have an energy fluence of about 40,000 ergs/cm^2 (40 J/m^2). The paper indicates (p. 83) that

supernova events release on the scale of 10^{49} to 10^{50} ergs (10^{42} to 10^{43} J) of gamma radiation. The paper asserts (pp. 85 to 86) that such an event has the potential to cause ozone depletion in earth's atmosphere for a period of two to six years and created nitrogen-rich environments at the earth's surface.

Observable effects are suggested to include kerogen-rich sediments at 11 sites worldwide. The effects are also stated to include short-term terrestrial global cooling. The paper also asserts that such events could precipitate increased ultraviolet-light penetration by ozone layer depletion. The increased intensity could be as much as 2 to 10 times the present level. Aside from the potential impact on ^{14}C dating, no other effects are discussed.

Extent and Quality of Corroborating Data—Ruderman (1976 [DIRS 167875]) corroborates that ozone depletion in the atmosphere could occur and that nitrogen-enriched surface conditions could result. Ruderman also cites the work of others and corroborates that supernova explosions result in energy release of 10^{48} to 10^{50} ergs (10^{41} to 10^{43} J). Ruderman briefly mentions that increased ultraviolet influx could have altered life through mutations or suppression. The paper mentions that there is no compelling fossil evidence for past biological cataclysms related to supernova events. Arnold (2003 [DIRS 167638], p. 127) also corroborates the assertions of Brakenridge. Arnold notes that considerable attention has been focused on "the possibility that climate change may be attributable to variations in galactic cosmic-ray fluxes that are modulated by the heliospheric magnetic field." Arnold further discusses the interaction between cosmic rays and the role of ionization trails in cloud formation. This interaction suggests a possible mechanism by which cosmic rays could modify climates. Similarly, Novotna and Vitek (1991 [DIRS 167634], p. 35) also discuss external forcing mechanisms and specifically mention galactic cosmic rays, solar cosmic rays, and equivalent particles from other sources, with galactic cosmic rays being the best candidate for both short-term and long-range forcing via the generation of additional cirrus clouds and subsequent temperature changes in the upper troposphere.

Further corroboration comes from Karam (2002 [DIRS 167872]), who calculates the potential gamma and neutrino radiation dose at and beneath the earth's surface resulting from supernovae and gamma ray bursts. The paper corroborates further the data included in the paper by Brakenridge by indicating that supernovae are noted as occurring at a frequency of about 1 to 2 per century.

J15.2.3 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the property of interest and the existence of corroborating data, the data from Brakenridge (1981 [DIRS 167873]) are appropriate for intended use and are qualified for use in the screening justification for FEP 1.5.01.02.0A (Extraterrestrial Events).

J16. FEP 1.5.03.01.0A – CHANGES IN THE EARTH'S MAGNETIC FIELD

This FEP uses data from the following journal article as direct input:

Biggin, A.J. and Thomas, D.N. 2003. "Analysis of Long-Term Variations in the Geomagnetic Polodial Field Intensity and Evaluation of Their Relationship with Global Geodynamics." *Geophysical Journal International, 152,* ([2]), 392-415. TIC: 255680. [DIRS 167876]

The data to be qualified for intended use within this FEP include:

> During the last 160 million years the number of pole reversals varies from 0 to 50 (Biggin and Thomas 2003 [DIRS 167876], Figure 11).

J16.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Biggin and Thomas (2003 [DIRS 167876]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use, as well as availability of corroborating data. Qualification process attributes used in the assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (# 3).
- Extent and quality of corroborating data or confirmatory testing results (# 10).

J16.2 CORROBORATING DATA

Data Demonstrates Properties of Interest—The property of interest is that pole reversals do occur and that they have been occurring. The last pole reversal occurred approximately 750,000 years ago and is known as the Matuyama-Brunhes Chron Boundary (Sarna-Wojcicki et al. 1997 [DIRS 109161]). It is not possible to predict the next occurrence of a pole reversal; however, any possible past influences are inherent to the geology of Yucca Mountain and would thus be included in analyses. No contradictory information exists indicating significant change to regional or smaller scale geologic or hydrologic systems due to variations in the earth's magnetic field, with the possible exception of a climate change relationship.

Extent and Quality of Corroborating Data—The direct input is from Figure 11 of Biggin and Thomas (2003 [DIRS 167876]). This information is corroborated in the paper by Johnson et al. (1995 [DIRS 185111], Figure 3), in which the timeframe of interest (160 My) is characterized by the highest relative reversal rate of ~60. The information can also be corroborated by data from Odenwald (2003 [DIRS 160892]), which was taken from a National Aeronautics and Space Administration-sponsored site.

J16.3 DATA QUALIFIED FOR INTENDED USE

The above discussion of the direct input provides an acceptable level of confidence that the data are suitable for their intended use, which is for FEP screening. The data described above are qualified for use within FEP 1.5.03.01.0A (Changes in Earth's Magnetic Field).

J17. FEP 1.5.03.02.0A – EARTH TIDES

This FEP uses data from the following journal article as direct input:

Bredehoeft, J.D. 1997. "Fault Permeability Near Yucca Mountain." *Water Resources Research, 33,* (11), 2459-2463. Washington, D.C.: American Geophysical Union. TIC: 236570. [DIRS 100007]

The data to be qualified for intended use within this FEP include:

> Earth tide effects in borehole UE-25 p#1 are cited in (Bredehoeft 1997 [DIRS 100007], p. 2,460), with measured fluctuations in groundwater levels of 2.05 cm.

These data are used to establish that water-level fluctuations in response to earth tides are minimally small (e.g., on the scale of a few centimeters or less), relative to their fluctuations in response to other processes.

J17.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Bredehoeft (1997 [DIRS 100007]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their intended use, and availability of corroborating data. Qualification process attributes used in the assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (# 3).
- Extent and quality of corroborating data or confirmatory testing results (# 10).

J17.2 CORROBORATING DATA TO BREDEHOEFT 1997

The paper by Bredehoeft (1997 [DIRS 100007]) is focused on the effects of fault permeability at Yucca Mountain. However, earth tides and other water-level fluctuations are specifically analyzed and the magnitude of the fluctuations is stated, which is the property of interest. The referenced information used from Bredehoeft (1997 [DIRS 100007]) is the fluctuation in groundwater levels of 2.05 cm in the deep carbonate aquifer penetrated by borehole UE-25p1. The author cites Galloway and Rojstaczer (1988 [DIRS 156826]) as a source of these data. Information on water-level fluctuations is corroborated by Fenelon (2000 [DIRS 160881]) and Luckey et al. (1996 [DIRS 100465]) as discussed below.

The fluctuation in groundwater level is explained by Kies et al. (1999 [DIRS 160882]) who state: "tidal forces deform the earth; effects induced on fluids near the surface of the earth are documented by the observations of water level changes in wells. These changes are driven by alterations of the pore pressure induced by tidal deformation of porous and fluid-saturated crustal material." These pressure changes can result in related effects such as fluctuations in underground gas concentrations (Kies et al. 1999 [DIRS 160882]) and water-level fluctuation in

wells (Fenelon 2000 [DIRS 160881], p. 14). Kies et al. (1999 [DIRS 160882]) indicate that strain variations induced by earth tides are very small (less than on the order of 10^{-8} strain per year), which would translate to minimal fluctuations in water levels. Corroboration that individual fluctuations are of low magnitude is provided by two studies. Water levels in boreholes at Paiute Mesa (on the Nevada Test Site) were analyzed for earth tide effects and the fluctuation due to earth tides was on the order of several hundredths of a foot (Fenelon 2000 [DIRS 160881], p. 14). Further corroboration is found in the paper by Luckey et al. (1996 [DIRS 100465], pp. 29 to 32), where the lack of consistent, large-magnitude variations in water levels observed in wells near Yucca Mountain is documented.

J17.3 DATA QUALIFIED FOR INTENDED USE

The above corroboration provides a suitable level of confidence that the data from Bredehoeft (1997 [DIRS 100007]) described above are appropriate for intended use; these data are qualified for use in the screening justification for FEP 1.5.03.02.0A (Earth Tides).

J18. FEP 2.1.02.08.0A – PYROPHORICITY FROM DSNF

This FEP uses data from the following report as direct input:

Garvin, L.J. 2002. *Multi-Canister Overpack Topical Report.* HNF-SD-SNF-SARR-005, Rev. 3. Richland, Washington: Fluor Hanford. ACC: MOL.20040510.0106. [DIRS 169141]

The data to be qualified for intended use within this FEP are:

> The maximum water in a sealed multi-canister overpack (MCO) is 4.64 kg (bound in particulate), with less than 200 g being present as free water (Garvin 2002 [DIRS 169141], Table 4-4).
>
> 1.1×10^7 g uranium metal per waste package, assuming that the waste package contains two MCOs and each MCO contains Mark IV fuel (3,804 kg U) and scrap (1,832 kg U) for a total of 5,636 kg U (Garvin 2002 [DIRS 169141], Table 4-4).
>
> The N Reactor SNF contained within MCOs emplaced inside the codisposal waste packages are dried and filled with helium (Garvin 2002 [DIRS 169141], Section 4.1.3.2).

J18.1 Qualification Method

The method of qualification for intended use of data from the report by Garvin (2002 [DIRS 169141]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The applicable elements of the Spent Nuclear Fuel Project QA program, documented in the source reference (Garvin 2002 [DIRS 169141], Section 13.0), and in the references cited therein, were also considered. The rationale for using these methods is that they were appropriate considering the extent of available documentation that allowed the evaluation of the methodology, data acquisition, and data review. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).
- The quality and reliability of the measurement control program under which the data were generated (#5).
- The extent to which conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).
- The degree to which independent audits of the process that generated the data were conducted (#11).

J18.2 Technical Assessment

The maximum acceptable MCO water mass data are used to estimate the amount of oxygen that may be available inside a sealed 2-MCO/2-DHLW waste package to support pyrophoric reactions, and thus the presence of scrap baskets are an important aspect.

The evaluation of the qualification of personnel generating the data, quality and reliability of the measurement control program, adequacy of the QA program, and the evidence of independent audits is presented in the documentation of qualification of data from the same report for FEP 2.1.13.01.0A (Radiolysis). It was concluded that the acceptance criteria for these attributes were met. Additional considerations are presented below.

Confidence in the Data Acquisition or Developmental Results is Warranted—The methods used to obtain the MCO fuel loading and water content data are described in footnotes "b," "g," and "h" and associated references in the cited data source (Garvin 2002 [DIRS 169141], Table 4-4). The estimate of the uranium-metal fuel mass loading was appropriately based on the design basis input description and the MCO design description. Estimates of the amount of bound water in the MCOs were based on estimates of the mass of the various particulates that contain bound water and detailed evaluation of the water content of these particulates. These methods are appropriate.

J18.3 Data Qualified for Intended Use

The results of the technical assessment presented above confirm that the specific data on mass of uranium (with scrap baskets), water amount in a sealed MCO, and conditions the N Reactor SNF is sealed under (Garvin 2002 [DIRS 169141], Section 2.2.6.2) are adequate and are qualified for their use in the screening justification for excluded FEP 2.1.02.08.0A (Pyrophoricity from DSNF).

J19. FEP 2.1.03.07.0A – MECHANICAL IMPACT ON WASTE PACKAGE

This FEP uses data from the following reports as direct input:

Multi-Canister Overpack Topical Report (Garvin 2002. [DIRS 169141])

State of the Art on the Helium Issues (Piron and Pelletier 2001 [DIRS 165318])

Calculation of Amount of Free Water Required to Overpressurize DOE SNF Standardized Canister and RW Waste Package (Wachs 2004 [DIRS 184624]).

J19.1 QUALIFICATION OF DATA FROM GARVIN 2002

Garvin, L.J. 2002. *Multi-Canister Overpack Topical Report.* HNF-SD-SNF-SARR-005, Rev. 3. Richland, Washington: Fluor Hanford. ACC: MOL.20040510.0106. [DIRS 169141]

The data to be qualified for intended use within this FEP include the following:

> The design pressure for the multi-canister overpack (MCO) is 450 psi (gauge) at 132°C (Garvin 2002 [DIRS 169141], Section 2.2.6.2).

J19.1.1 Qualification Method

The method of qualification for intended use of data from the report by Garvin (2002 [DIRS 169141]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The applicable elements of the Spent Nuclear Fuel Project QA program, documented in the source reference (Garvin 2002 [DIRS 169141], Section 13.0) and in the references cited therein, were also considered. The rationale for using these methods is that they were appropriate considering the extent of available documentation that allowed the evaluation of the methodology, data acquisition, and data review. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).
- The quality and reliability of the measurement control program under which the data were generated (#5).
- The extent to which conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).
- The degree to which independent audits of the process that generated the data were conducted (#11).

J19.1.2 Technical Assessment

The evaluation of the qualification of personnel generating the data, quality and reliability of the measurement control program, adequacy of the QA program, and the evidence of independent audits is presented in the documentation of qualification of data from the same report for FEP 2.1.13.01.0A (Radiolysis). It was concluded that the acceptance criteria for these attributes were met. The design pressure and temperature are used to evaluate the potential for MCO failure from internal pressurization due to gas generation and temperature changes during the first 10,000 years after repository closure. Additional considerations are presented below.

Confidence in the Data Acquisition or Developmental Results is Warranted—The MCO provides confinement of SNF and maintains the SNF in a critically safe configuration. The MCO's structural design has been developed in accordance with the ASME Boiler and Pressure Vessel Code (ASME 1998 [DIRS 155708], Section III, "Rules for Construction of Nuclear Power Plant Components," Subsection NB), consistent with NRC requirements for a 10 CFR Part 72 licensed facility (Garvin 2002 [DIRS 169141], Section 1.2). In addition, the design of the MCO has been reviewed to identify any additional actions, beyond existing DOE requirements, that were necessary to demonstrate nuclear safety equivalence to comparable NRC-licensed facilities (Garvin 2002 [DIRS 169141], Section 1.6).

The design of the MCO has been prepared in accordance with the NRC's design and quality assurance requirements for nuclear power plant components. The stringent nuclear safety requirements provide a level of confidence that the QA program under which the report was generated at least partially meets the QA program that supports the YMP license application process or postclosure science.

J19.1.3 Data Qualified for Intended Use

The results of the technical assessment presented above confirm that the design pressure and temperature for the MCO (Garvin 2002 [DIRS 169141], Section 2.2.6.2) are adequate and are qualified for their use in the screening justification for excluded FEP 2.1.03.07.0A (Mechanical Impact on Waste Package).

J19.2 QUALIFICATION OF DATA FROM PIRON AND PELLETIER 2001

Piron, J.P. and Pelletier, M. 2001. "State of the Art on the Helium Issues." Section 5.3 of *Synthesis on the Long Term Behavior of the Spent Nuclear Fuel.* Poinssot, C., ed. CEA-R-5958(E). Volume 1. Paris, France: Commissariat à l'Énergie Atomique. TIC: 253976. [DIRS 165318]

The data to be qualified for intended use within this FEP are the following:

> The decay helium gas pressure is 90 bars at 20°C in commercial spent nuclear fuel rods with a gap volume of 13 cm^3 and a burnup of 47.5 GWd/MTU after 10,000 years (Piron and Pelletier 2001 [DIRS 165318], Section 5.3.2.4.1).

J19.2.1 Qualification Method

The method of qualification for intended use of the data from the report by Piron and Pelletier (2001 [DIRS 165318]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2) in accordance with SCI-PRO-005, Section 3. The rationale for using this method is that it was the most suitable considering the data, their intended use, and availability of corroborating data. Qualification process attributes used in the data qualification were selected from the list provided in Attachment 4 of SCI-PRO-001.

> Attribute specifically applicable to these data is extent and quality of corroborating data (#10).

J19.2.2 Corroborating Data

The corroborating data used are decay helium inventory and actinide radionuclide inventory data at 1,000 years for spent nuclear fuel rods with a burnup of 45 GWd/MTU (Guenther et al. 1991 [DIRS 109207], p. D.78).

Description of Qualification Approach and Results—The approach is to use the corroborating data to independently calculate the gap pressure that would occur from the He gas generated as a result of alpha particle decay after 10,000 years.

The steps involved in this calculation are:

- Listing the inventories of decay helium and principal alpha-emitting radionuclides (^{241}Am, ^{240}Pu, ^{239}Pu, and ^{243}Am) in commercial SNF at 1,000 years (Guenther et al. 1991 [DIRS 109207], p. D.78).

- Estimating the change in the helium inventory that will result from alpha decay during the period between 1,000 years and 10,000 years and adding this change to the 1,000-year helium inventory.

- Calculating the pressure at 20°C in the void volume of a fuel rod from the helium gas generated as a result of alpha particle decay at 10,000 years.

The calculations are analogous to those performed for qualifying the data from the same reference for FEP 2.1.12.02.0A (Gas Generation (He) from Waste Form Decay), except that the calculations for this FEP concern the helium gas pressure increase at 20°C (293 K) within the void volume of a fuel rod (13 cm^3), whereas the calculations for FEP 2.1.12.02.0A concern the pressure increase at 50°C (323 K) in the void volume of a commercial SNF waste package (4,737 L).

The amount of helium in a commercial SNF waste package with average burnup of 45 GWd/MTU was 7.3E2 g (1.83E2 gmol He) from the section on corroborating data in FEP 2.1.12.02.0A (Gas Generation (He) From Waste Form Decay). For 21 PWR fuel assemblies with 208 rods per assembly, the amount of helium gas per fuel rod is 4.19×10^{-2} gmol He (1.83E2 gmol He ÷ 21 assemblies ÷ 208 rods per assembly). From the ideal gas law, pV = nRT, where n = 4.19E-2 gmol He; R = 8.3143 N-m/mol/K; T = 293 K, V = 0.000013 m^3;

the resulting pressure is p = 7.86 × 10^6 N/m^2 = 7.86 × 10^6 Pa = 78.5 bars (R, gas constant, rounded and unit conversion from Weast 1985 [DIRS 111561]). The resulting pressure values of 78.5 bar compared to 90 bar (Piron and Pelletier 2001 [DIRS 165318]) is close (within 15%), such that the corroboration is sufficient to meet the needs for the intended use within the FEP.

The calculated pressure that would result from release of the decay helium into the fuel rod gap is 78.5 bars at 20°C after 10,000 years. This value compares favorably with the gap pressure of 90 bars at 20°C after 10,000 years from Piron and Pelletier 2001 ([DIRS 165318], Section 5.3.2.4.1). This result confirms that the gap pressure at 10,000 years from Piron and Pelletier (2001 [DIRS 165318], Section 5.3.2.4.1) is adequate and slightly conservative for its use in excluded FEP 2.1.03.07.0A (Mechanical Impact on Waste Package). The pressure and temperature in the fuel rod gap are used to estimate the pressure change in a waste package if all of the He gas generated as a result of alpha particle decay over 10,000 years was released from the fuel rods into the void volume of a TAD-bearing waste package with commercial SNF.

J19.2.3 Data Qualified for Intended Use

The results of the data evaluation provides a sufficient level of confidence that the data from the publication by Piron and Pelletier (2001 [DIRS 165318]) are appropriate for intended use. The data are qualified use in the screening justification for excluded FEP 2.1.03.07.0A (Mechanical Impact on Waste Package).

J19.3 QUALIFICATION OF DATA FROM WACHS 2004

Wachs, G. 2004. *Calculation of Amount of Free Water Required to Overpressurize DOE SNF Standardized Canister and RW Waste Package.* EDF-NSNF-017, Rev. 1. Washington, D.C.: U.S. Department of Energy, National Spent Nuclear Fuel Program. ACC: LLR.20080109.0001. [DIRS 184624]

The data to be qualified for intended use within this FEP are the following:

> The volume of free (unbound) water is approximately 0.0005 liters in a 15-foot-long DOE SNF Standardized Canister after cold vacuum drying (Wachs 2004 [DIRS 184624], Section 6).

J19.3.1 Qualification Method

The method of qualification for intended use of the data from the report by Wachs (2004 [DIRS 184624]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5) in accordance with SCI-PRO-005, Section 3. The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the data qualification were selected from the list provided in Attachment 4 of SCI-PRO-001.

Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).

- The quality and reliability of the measurement control program under which the data were generated (#5).

- The extent to which conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).

J19.3.2 Technical Assessment

This report originates from the National Spent Nuclear Fuel Program (NSNFP) with the specific purpose to calculate the minimum amount of free water and physically adsorbed water that if completely dissociated could approach the pressure limits within a DOE SNF Standardized canister. This program works under NSNFP Quality Assurance, which implements *Quality Assurance Requirements and Description* (Wachs 2004 [DIRS 184624], p. 9, Quality Assurance). An external reviewer approving the document (Wachs 2004 [DIRS 184624], p. 1), added confidence that the data are reliable.

This QA program is the same as that evaluated for Garvin (2002 [DIRS 169141]) in FEP 2.1.13.01.0A (Radiolysis). The evaluation of the qualification of personnel generating the data, quality and reliability of the measurement control program, adequacy of the QA program, and the evidence of independent audits is presented in the documentation of qualification of data from the same report for FEP 2.1.13.01.0A (Radiolysis). It was concluded that the acceptance criteria for these attributes were met. Additional considerations are presented below.

Extent to Which the Data Demonstrate the Properties of Interest—The volume of free water is used to estimate the pressure of water vapor in a codisposal waste package at its peak temperature of 191.0°C, shortly after repository closure. Considering the dimensions of a waste package are much larger than the dimensions of a MCO or SNF Standard canister, the relative amount of free water per canister is relatively small compared to the void volume of the waste package. Additionally, high-level waste such as that under consideration for the intended use of this data should not contain sufficient amounts of water to appreciably add to the water contained in the waste package (Wachs 2004 [DIRS 184624], p. 5).

The source document *Calculation of amount of free water required to overpressurize DOE SNF Standardized Canister and RW Waste Package* (Wachs 2004 [DIRS 184624]) was prepared for the National Spent Nuclear Fuel Project similar to the needs of YMP.

J19.3.3 Data Qualified for Intended Use

Based on this technical assessment, and consideration of the qualification process attributes listed above, the data from the report by Wachs (2004 [DIRS 184624]) are appropriate and qualified for their use in the screening justification for excluded FEP 2.1.03.07.0A (Mechanical Impact on Waste Package).

J20. FEP 2.1.03.10.0B – ADVECTION OF LIQUIDS AND SOLIDS THROUGH CRACKS IN THE DRIP SHIELD

This FEP uses data from the following journal article as direct input:

Siriwardane, R.V. and Wightman, J.P. 1983. "Interaction of Hydrogen Chloride and Water with Oxide Surfaces. III. Titanium Dioxide." *Journal of Colloid and Interface Science, 94,* (2), 502-513. New York, New York: Academic Press. TIC: 259837. [DIRS 183688]

The data to be qualified for intended use within this FEP and Appendix C include:

> Specific surface area (6 to 50 m^2/g) of commercial-grade crystalline rutile and anatase (Siriwardane and Wightman 1983 [DIRS 183688], p. 504).

These data are to be used as a conservative estimate of specific surface area for the corrosion product within cracks of the drip shield. Specific surface area is one of the parameters in the equation for estimating saturated hydraulic conductivity of corrosion products in Appendix C. The corrosion product particles are expected to be a few tens of nanometers in size (He et al. 2007 [DIRS 183687], p. 789 and Figure 14-b), and particles of this description are estimated to have specific surface area on the order of 100 m^2/g (Yao and Zhang 1999 [DIRS 184766], Tables I and II). Because the data range is smaller than what is anticipated, the use of the data is a conservative approach within the FEP and associated calculations in Appendix C.

J20.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Siriwardane and Wightman (1983 [DIRS 183688]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their intended use, and availability of corroborating data. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J20.2 CORROBORATING DATA FOR SIRIWARDANE AND WIGHTMAN 1983

The data described above represent a range of specific surface area values from these commercial sources. The article Siriwardane and Wightman (1983 [DIRS 183688]) uses multiple commercial sources of rutile and anatase. Depending on the synthetic method employed, rutile and anatase can have a wide range in specific surface areas. For example, the method of preparation and resulting specific surface area found in the study by Yao and Zhang (1999 [DIRS 184766], Table I) is on the order of 100 m^2/g. The specific surface area of another commercial source of rutile, found in the journal article by Nag et al. (2007 [DIRS 184817], Table 2), similar in particle size to that under discussion, is on the order of 3 m^2/g. These additional sources corroborate the available range of commercially available rutile and anatase in

the article by Siriwardane and Wightman (1983 [DIRS 183688]) as adequate for the intended use within this FEP. The data range used in the FEP represents a conservative approach and is adequate and accurate for the intended use of the data.

J20.3 DATA QUALIFIED FOR INTENDED USE

The assessment presented above provides sufficient confidence that the data from the article by Siriwardane and Wightman (1983 [DIRS 183688]) are adequate for intended use and are qualified for use in the screening justification for FEP 2.1.03.10.0B (Advection of Liquids and Solids through Cracks in the Drip Shield).

J21. FEP 2.1.06.01.0A – CHEMICAL EFFECTS OF ROCK REINFORCEMENT AND CEMENTITIOUS MATERIALS IN EBS

This FEP uses data from the following reference as direct input:

Ziegler, J.D. 2004. "Transmittal of Appendix D of the Technical Basis Document No. 10: Unsaturated Zone Transport Addressing Key Technical Issue (KTI) Agreement Evolution of Near-Field Environment (ENFE) 1.04." Letter from J.D. Ziegler (DOE/ORD) to the NRC, August 31, 2004, 0902043035, OLA&S:JCP-1434 with enclosure. ACC: MOL.20041027.0242. [DIRS 171694]

The data are taken from the enclosure to the letter. The data to be qualified for intended use within this FEP include:

> Water in equilibrium with portlandite-hillebrandite contains 625 mg total Ca/kg water (Ziegler 2004 [DIRS 171694], Table D-12), which is equivalent to approximately 1.56×10^{-2} mol Ca/kg water.

J21.1 QUALIFICATION METHOD

The qualification method of the data from Ziegler (2004 [DIRS 171694]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). Corroborating data are available for comparison with the unqualified data set and any inferences drawn to corroborate the unqualified data can be clearly identified, justified, and documented. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Extent to which the data demonstrate the properties of interest (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J21.2 CORROBORATING DATA

The strategy taken to corroborate the data from Ziegler (2004 [DIRS 171694]) was to determine the calcium concentration independently. These calculations were carried out using the qualified computer code EQ3/6 V.8.1 (STN: 10813-8.1-00 [DIRS 176889]); direct input data were obtained from thermodynamic database (DTN: SN0612T0502404.014 [DIRS 178850], file: *data0.ymp.R5*). The objective of these calculations was to predict the concentration of calcium in solution in the presence of hillebrandite at 25°C and 1 bar. The results of calculations are included in DTN: SN0712CEMENTEQ.001. Caveats and limitations of the calculations are also documented within the same DTN and are appropriate for the intended use of the data.

To corroborate the data from the report by Ziegler (2004 [DIRS 171694]), comparison of the calcium concentrations was made between the results of the calculations described above (included in the output file *portland-hws.3o* in the output DTN: SN0712CEMENTEQ.001) and those from Ziegler (2004 [DIRS 171694]) (as found in the file output file *output.portlandite* in the unqualified DTN: LB0408CMATUZFT.004 [DIRS 171706]). Summary of the main results is provided in Table J21-1. These results indicate that the differences between the two

simulations are small (within 1%; see Table J21-1). It is noted that a comparison of predicted SiO_2(aq) concentration between the two code run outputs shows differences by a factor of approximately 2. This discrepancy is due to differences in the thermodynamic data used for SiO_2(aq) in the EQ3/6 calculations by Ziegler (2004 [DIRS 171694]), (presented in *output.portlandite*) and the data used in the present calculations. This difference in SiO_2 (aq) concentration does not affect the prediction of portlandite solubility given by the total Ca concentration, and the solubility of this phase is the focus of the current comparison. In fact, differences in the predicted total Ca concentrations given in the files *output.portlandite* and *portland-hws.3o* are less than 1%, and are negligible for the intended use of the data. In addition, the differences in predicted pH values are also less than 1%. Table J21-1 below summarizes the main results of the equilibrium solubility calculations given by the output files *output.portlandite* and *portland-hws.3o*. Given the close agreement in the prediction of Ca concentrations for portlandite- hillebrandite solubility, this result confirms the validity of the used for portlandite solubility in Ziegler (2004 [DIRS 171694]).

Within the scope of this criterion, added confidence in the data is given by their qualification process attributes as discussed below and outlined in Attachment 4 of SCI-PRO-001.

Extent to Which the Data Demonstrate the Properties of Interest—The data presented by Ziegler (2004 [DIRS 171694]) provide solubility values for portlandite- hillebrandite. The solubility of portlandite is used in the assessment of the alkaline cement leachate stability. Exposure of the cement leachate to CO_2 leads to plume carbonation and thus its neutralization. It is assumed that the leachate is saturated with respect to portlandite-hillebrandite and the total Ca concentration in solution is sufficient to allow for calcite precipitation as a result of the plume neutralization.

Extent and Quality of Corroborating Data or Confirmatory Testing Results—Table J21-1 below shows a comparison of EQ3/6 code outputs from the code runs performed in this analysis (output DTN: SN0712CEMENTEQ.001) and the data by Ziegler (2004 [DIRS 171694]) (DTN: LB0408CMATUZFT.004 ([DIRS 171706]). Notice the strong agreement (difference less than 1%) between the two outputs for total Ca concentration and pH. These two parameters define portlandite in the presence of hillebrandite solubility.

Table J21-1. Summary of Main Results of EQ3/6 Equilibrium Solubility Calculations

Phase Assemblage	Total SiO_2(aq)[1] (mg/kg H_2O)	Total SiO_2(aq)[2] (mg/kg H_2O)	Total Ca[1] (mg/kg H_2O)	Total Ca[2] (mg/kg H_2O)	pH[1]	pH[2]
Portlandite-hillebrandite	0.14	0.27	625	630	12.37	12.375

[1] Ziegler 2004 [DIRS 171694], Table D-12.
[2] Ouput DTN: SN0712CEMENTEQ.001 (rounded).

J21.3 DATA QUALIFIED FOR INTENDED USE

The data specified above from Ziegler (2004 [DIRS 171694]) are appropriate for intended use within FEP 2.1.06.01.0A (Chemical Effects of Rock Reinforcement and Cementitious Materials in EBS). Based on the extent to which the data demonstrate the properties of interest and the existence of corroborating data by using the qualified code and the thermodynamic database, the data can be considered qualified for use in the screening justification for this FEP.

J22. FEP 2.1.06.06.0B – OXYGEN EMBRITTLEMENT OF DRIP SHIELDS

This FEP uses data from the following journal article as a direct input:

Rogers, J.W., Jr.; Erickson, K.L.; Belton, D.N.; Springer, R.W.; Taylor, T.N.; and Beery, J.G. 1988. "Low Temperature Diffusion of Oxygen in Titanium and Titanium Oxide Films." *Applied Surface Science, 35,* 137-152. Amsterdam, The Netherlands: North-Holland. TIC: 259889. [DIRS 184108]

The data to be qualified for intended use within this FEP include:

> The value of the diffusion coefficient of oxygen in titanium at 300°C is 8.8×10^{-18} cm^2 s^{-1} and has an uncertainty of 70% (Rogers et al. 1988 [DIRS 184108], Table 1 and p. 146).

J22.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Rogers et al. (1988 [DIRS 184108]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes considered to assess the appropriateness of this external data for the intended use are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

J22.2 TECHNICAL ASSESSMENT

The journal article by Rogers et al. (1988 [DIRS 184108]) contains values of oxygen diffusion coefficients in titanium metal and titanium oxide films at various elevated temperatures. These values are based on results of experiments conducted by researchers at Sandia and Los Alamos National Laboratories, both of which are top-level research organizations in the United States of America. These results were published in 1988 in *Applied Surface Science*, a peer-reviewed scientific journal published from The Netherlands. The datum with its associated uncertainty of 70% is used in this FEP screening qualification to represent the oxygen diffusion coefficient in titanium metal at 300°C (573 K). The article by Rogers et al. (1988 [DIRS 184108]) contains measured values of oxygen diffusion coefficients in titanium metal at 300°C (573 K) and above. Thus, this datum (i.e., 8.8×10^{-18} cm^2 s^{-1}) belongs to a data set that represents the material property of interest to a significant extent.

J22.3 DATA QUALIFIED FOR INTENDED USE

Based on the qualifications of the researchers, the reputations of the organizations generating data, and the extent to which the data demonstrate the properties of interest, the data from the journal article by Rogers et al. (1988 [DIRS 184108]) are appropriate for intended use and are qualified for use in the screening justification for FEP 2.1.06.06.0B (Oxygen Embrittlement of Drip Shields).

J23. FEP 2.1.09.13.0A – COMPLEXATION IN EBS

This FEP uses data from the following article:

Means, J.L.; Maest, A.S.; and Crerar, D.A. 1983. *The Organic Geochemistry of Deep Ground Waters and Radionuclide Partitioning Experiments under Hydrothermal Conditions.* ONWI-448. Columbus, Ohio: Battelle Memorial Institute, Office of Nuclear Waste Isolation. TIC: 209098. [DIRS 100797]

The data to be qualified for intended use within this FEP include:

> Total organic carbon is 0.58 mg/L for well UE25b-1 (Means et al. 1983 [DIRS 100797], Table 1), 33% (0.19 mg/L) of which has a molecular weight greater than 1,000 (Means et al. 1983 [DIRS 100797], Table 3).

J23.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Means et al. (1983 [DIRS 100797]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes considered to assess the appropriateness of this project data for the intended use are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The technical adequacy of equipment and procedures used to collect and analyze the data (#2)

J23.2 TECHNICAL ASSESSMENT

The data under consideration is from the technical report by Means et al. (1983 [DIRS 100797]) prepared as a summary of research activities from several potential repository sites in the United States. Samples from the Nevada Test Site were collected and stored at room temperature in polyethylene-lined 55-gallon drums, and were provided to the authors by A.E. Ogard of Los Alamos National Laboratory (Means et al. 1983 [DIRS 100797], p. 1). The methods of analysis are well documented within the report by Means et al. (1983 [DIRS 100797], pp. 4, 5, 7) and consist of standard technical methods for the analysis of total organic carbon. The equipment used is an organic carbon analyzer, specific to this type of assay. It has sufficient resolution to warrant confidence in the results. Gel filtration chromatography (based on size exclusion) was used to obtain semi-quantitative estimates of the molecular weight distributions of natural organic compounds present (Means et al. 1983 [DIRS 100797], p. 12). Further confidence in the results is obtained as the mean value is reported from nine analyses. The results of these

analyses are documented within the report by Means et al. (1983 [DIRS 100797], pp. 7, 17, 18, Tables 1 and 3). The methods outlined by Means et al. (1983 [DIRS 100797]) were used as a comparison in a separate determination by Minai et al. (1992 [DIRS 100801]), adding to the level of confidence that these methods are suitable for the intended use.

Jeffrey L. Means has published multiple articles on the topic of organic geochemistry specifically from groundwaters and the relationship between adsorption with actinides over the last ~30 years as demonstrated by the references within the report by Means et al. (1983 [DIRS 100797]). Based upon his publication record, he is considered an expert in his field.

J23.3 DATA QUALIFIED FOR INTENDED USE

The data specified above from Means et al. (1983 [DIRS 100797]) are appropriate for intended use within FEP 2.1.09.13.0A (Complexation in EBS). Based on the qualifications of the personnel and the technical adequacy of the equipment and procedures used to collect and analyze the data, the data can be considered qualified for use in the screening justification for this FEP.

J24. FEP 2.1.09.15.0A – FORMATION OF TRUE (INTRINSIC) COLLOIDS IN EBS

This FEP uses data from the following journal articles:

"Actinide Behavior in Natural Waters" (Choppin and Stout 1989 [DIRS 168379])

"Properties of Plutonium (IV) Polymer of Environmental Importance" (Rai and Swanson 1981 [DIRS 144599])

"Ten-Year Results from Unsaturated Drip Tests with UO_2 at 90°C: Implications for the Corrosion of Spent Nuclear Fuel" (Wronkiewicz et al., 1996 [DIRS 102047])

"The Corrosion of Uraninite Under Oxidizing Conditions" (Finch and Ewing 1992 [DIRS 113030]).

J24.1 QUALIFICATION OF DATA FROM CHOPPIN AND STOUT 1989

Choppin, G.R. and Stout, B.E. 1989. "Actinide Behavior in Natural Waters." *Science of the Total Environment, 83,* ([3]), 203-216. Amsterdam, The Netherlands: Elsevier. TIC: 255706. [DIRS 168379]

The information to be qualified for intended use within this FEP include:

> For the higher charged actinides, hydrolysis can lead to formation of oligomers and polymers. At the low environmental concentrations of actinides, these are usually a problem only for Pu(IV), whose hydrolytic polymers are rather intractable (Choppin and Stout 1989 [DIRS 168379], p. 209).

J24.1.1 Qualification Method

The method of qualification for intended use of the data from the article by Choppin and Stout (1989 [DIRS 168379]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or developmental results was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviewers of the data and their results (#8).

J24.1.2 Technical Assessment

Qualifications of Personnel—G. R. Choppin is a well known and respected professional in the technical area of radionuclide chemistry and reactivity. Choppin was contributor and editor to symposium series 216 *Plutonium Chemistry* (Choppin 1983 [DIRS 168395]), has written multiple journal articles (e.g., Choppin 1992 [DIRS 100717]; Choppin 2003 [DIRS 168308]; Choppin 1986 [DIRS 168377]) on the topic of plutonium chemistry, and is regarded as an expert in the field. Choppin's work is published in well-respected journals, which adds confidence in the qualifications of personnel.

Extent to Which the Data Demonstrate the Properties of Interest—The information under consideration reflects a convergent result that polymerization of actinides can take place and that Pu(IV) is the most important. This information demonstrates a well-studied set of observations culminating in a technical statement that becomes a well-accepted position within the scientific field. This statement is corroborated by several other references studied to date on plutonium chemistry by these authors and others (e.g., Rai and Swanson 1981 [DIRS 144599]; Toth et al. 1983 [DIRS 168394]).

Prior Peer and Other Professional Reviews—The paper on actinide behavior in natural waters was published in *Science of the Total Environment*, a well-known, international, peer-reviewed journal for scientific research into the environment and its relationship with humans. The reviewers of the articles submitted for publication in *Science of the Total Environment* are matched to the paper according to their expertise. They are requested to evaluate not only the technical content and organization of the article but also documentation of quality assurance and control, the data presented, and the quality of interpretation and conclusions.

The journal, published by Elsevier, is an international medium for publication of original research on the environment with emphasis on changes caused by human activities. It is concerned with changes in the natural levels and distribution of chemical elements and their compounds that may affect the well-being of the living world, or represent a threat to human health. The scope is multidisciplinary and international and the subjects covered include: (a) all aspects of the contamination or pollution of air, water, soil, and the human food chain; (b) natural and human-induced environmental changes at the global, regional, and local levels; (c) environmental risk management, remediation and treatment, and environmental policy appraisal; (d) effects on human and ecosystem health related to abnormalities in the level and distribution of chemical elements and their compounds in the environment; (e) novel techniques and methods of chemistry and biochemistry applicable to environmental problems and environmental health; (f) gene-environment interactions. The impact factor for this journal in 2006 was 2.359.

J24.1.3 Data Qualified for Intended Use

The information specified above from Choppin and Stout (1989 [DIRS 168379]) are appropriate for intended use within FEP 2.1.09.15.0A (Formation of True (Intrinsic) Colloids in EBS). Based on satisfactorily meeting the combined attributes specified, the information is be considered qualified for use in the screening justification for this FEP.

J24.2 QUALIFICATION OF DATA RAI AND SWANSON 1981

Rai, D. and Swanson, J.L. 1981. "Properties of Plutonium(IV) Polymer of Environmental Importance." *Nuclear Technology, 54,* (1), 107-112. La Grange Park, Illinois: American Nuclear Society. TIC: 221390. [DIRS 144599]

The data to be qualified for intended use within this FEP include:

> Pu(IV) polymer does not make stable suspensions at pH values above 5 and hence would not be expected to be mobile as polymer in the lithosphere (Rai and Swanson 1981 [DIRS 144599]. p. 111).

J24.2.1 Qualification Method

The method of qualification for intended use of the data from the article by Rai and Swanson (1981 [DIRS 144599]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or developmental results was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviewers of the data and their results (#8).

J24.2.2 Technical Assessment

Qualifications of Personnel—D. Rai and J.L. Swanson are well known experts in the technical area of radionuclide solubility chemistry and speciation (see for example the number of entries in the Technical Information Center). Their work is published in well-respected journals, which adds confidence in the qualifications of personnel.

Extent to Which the Data Demonstrate the Properties of Interest—The information under consideration reflects a convergent result that polymerization of actinides can take place and that Pu(IV) is the most important. This information demonstrates a well studied set of observations culminating in a technical statement that becomes a well-accepted position within the scientific field. Furthermore, the methods used in the determination of Pu(IV) polymer properties are appropriate for the type of data obtained. These methods include fundamental chemical redox assays and standard separation techniques.

Prior Peer and Other Professional Reviews—These data were subjected to professional reviews for inclusion in the IUPAC-NIST Solubility Data Series in the review article by Hala and Miyamoto 2007 [DIRS 185095], p. 1692 and 1703). The lead author, Dhanpat Rai, has authored or co-authored at least 13 peer-reviewed journal articles on plutonium chemistry over the past 30 years, and has provided expertise on actinide chemistry and expected behavior in the nuclear waste environment to the DOE since the late 1970s.

J24.2.3 Data Qualified for Intended Use

The data specified above from Rai and Swanson (1981 [DIRS 144599], p. 111) are appropriate for intended use within FEP 2.1.09.15.0A (Formation of True (Intrinsic) Colloids in EBS). Based on satisfactorily meeting the combined attributes specified, the information is considered qualified for intended use within this FEP.

J24.3 QUALIFICATION OF DATA FROM WRONKIEWICZ ET AL., 1996

Wronkiewicz, D.J.; Bates, J.K.; Wolf, S.F.; and Buck, E.C. 1996. "Ten-Year Results from Unsaturated Drip Tests with UO_2 at 90°C: Implications for the Corrosion of Spent Nuclear Fuel." *Journal of Nuclear Materials, 238,* (1), 78-95. Amsterdam, The Netherlands: North-Holland. TIC: 243361. [DIRS 102047]

The data to be qualified for intended use within this FEP include:

> Size-fractioned analyses revealed that between 1% and 12% of the total amount of uranium was present as a >5 nm size-fraction (the suspended fraction trapped by the filter) (Wronkiewicz et al. 1996 [DIRS 102047], p. 86).

J24.3.1 Qualification Method

The method of qualification for intended use of the data from the article by Wronkiewicz et al. (1996 [DIRS 102047]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or developmental results was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviewers of the data and their results (#8).

J24.3.2 Technical Assessment

Technical Adequacy of Equipment and Procedures Used—The experimental apparatus and materials, summarized within the article, are adequate and appropriate for the data collected. Additional documentation of the equipment, methods, and procedures used can be found in sources referenced by Wronkiewicz et al. (1991 [DIRS 176891]) and published by Wronkiewicz et al. (1992 [DIRS 100493]).

Extent to Which the Data Demonstrate the Properties of Interest—The original intended use of the information and data collected within this paper was for the Yucca Mountain Site Characterization Project, as part of its spent fuel scientific investigations. The data under consideration is from the latter years of testing; total testing was performed for 8 to 10 years. Because this data originates from the latter time period, there is sufficient confidence in the data collected and analyzed due to the fact that there were larger volumes of leachate available for sampling. Thus, the determination of uranium release by size fraction was able to be performed, which is the specific property of interest.

Prior Peer and Other Professional Reviews—The paper by Wronkiewicz et al. (1996 [DIRS 102047]) was published in *Journal of Nuclear Materials*. This publication is a peer-reviewed scientific journal that publishes high-quality papers in materials research relevant to nuclear fission and fusion reactors and high power accelerator technologies, and in closely related aspects of materials science and engineering. Both original research and critical review papers covering experimental, theoretical, and computational aspects of either fundamental or applied nature are welcome. The breadth of the field is such that a wide range of processes and properties is of interest to the readership, spanning atomic lattice defects, microstructures, thermodynamics, corrosion, and mechanical and physical properties, for example. The journal is published by Elsevier. The reviewers of the articles submitted for publication in *Journal of Nuclear Materials* are requested to evaluate not only the technical content and organization of the article but also documentation of quality assurance and control, the data presented, and the quality of interpretation and conclusions. The impact factor of this journal in 2006 was 1.261. Furthermore, this report was reviewed by YMP personnel prior to submission and acceptance by *Journal of Nuclear Materials* (see records package for DTN: LL960905751021.019 [DIRS 185101]).

J24.3.3 Data Qualified for Intended Use

The data specified above from Wronkiewicz et al. (1996 [DIRS 102047], p. 86) are appropriate for intended use within FEP 2.1.09.15.0A (Formation of True (Intrinsic) Colloids in EBS). Based on satisfactorily meeting the combined attributes specified, the information is considered qualified for intended use in this FEP.

J24.4 QUALIFICATION OF DATA FROM FINCH AND EWING 1992

Finch, R.J. and Ewing, R.C. 1992. "The Corrosion of Uraninite Under Oxidizing Conditions." *Journal of Nuclear Materials, 190,* 133-156. Amsterdam, The Netherlands: Elsevier. TIC: 246369. [DIRS 113030]

The information to be qualified for intended use within this FEP includes:

> The effect of dissolved silica on the alteration of the UOHs (uranyl oxide hydrates) is profound; the alteration of schoepite can result in the formation of uranyl silicates such as uranophane and soddyite (Finch and Ewing 1992 [DIRS 113030], Section 4.2.2).

J24.4.1 Qualification Method

The method of qualification for intended use of the data from the article by Finch and Ewing (1992 [DIRS 113030]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that corroborating data are available and inferences drawn to corroborate can be clearly identified, justified, and documented. The technical assessment was based on the determination that confidence in the data acquisition or developmental results was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviewers of the data and their results (#8).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J24.4.2 Technical Assessment

Extent to Which Data Demonstrate the Properties of Interest—The information under consideration reflects a convergent result that dissolved silica alters uranyl oxide hydrates by the formation of uranyl silicates. This information demonstrates a well-studied set of observations culminating in a technical statement that becomes a well-accepted position within the scientific field. The statement is further substantiated within the article by the phase diagram (Finch and Ewing 1992 [DIRS 113030], Figure 9). The relevance and quality of the data in this article may be inferred from the observation that, according to SearchPlus, it has been cited 129 times since its publication in 1992, and has averaged 11 citations per year over the past 10 years.

Prior Peer and Other Professional Reviews—The paper by Finch and Ewing was published in *Journal of Nuclear Materials*, a peer-reviewed scientific journal in the field of material research relevant to nuclear installations. This journal and its review requirements were discussed in the section describing the previous data being qualified for intended use in this FEP.

Extent and Quality of Corroborating Data—The statement that, in the presence of silica, uranyl oxide hydrates form uranyl silicates is corroborated by the work done by others. For

example, Wronkiewicz (1992 [DIRS 100493]) demonstrates that UOHs formed early and were subsequently altered to soddyite, followed by uranophane and boltwoodite. Frondel (1958 [DIRS 113267]) characterizes the complete replacement of uraninite by uranophane as a common occurrence, substantiating the technical information that uranyl silicates can form.

J24.4.3 Data Qualified for Intended Use

The data specified above from Finch and Ewing (1992 [DIRS 113030], Section 4.2.2) are appropriate for intended use within FEP 2.1.09.15.0A (Formation of True (Intrinsic) Colloids in EBS). Based on satisfactorily meeting the combined attributes specified, the information is be considered qualified for intended use in the screening justification for this FEP.

J25. FEP 2.1.09.21.0A – TRANSPORT OF PARTICLES LARGER THAN COLLOIDS IN EBS

This FEP uses information from the following reference as direct input:

Reimus, P.W. 1995. *Transport of Synthetic Colloids Through Single Saturated Fractures: A Literature Review.* LA-12707-MS. Los Alamos, New Mexico: Los Alamos National Laboratory. ACC: MOL.19950302.0063. [DIRS 144604]

> The data to be qualified for intended use, obtained from the report by Reimus (1995 [DIRS 144604], Sections 3.2 and 3.3), supports the statement that inorganic particles larger than 1 μm will settle much more rapidly than they diffuse.

Description, justification of the equations and qualification of the data pertaining to the behavior of small particles transported through fractures in the saturated zone is presented in this appendix under the discussion for FEP 2.1.09.21.0B (Transport of Particles Larger than Colloids in the SZ). The use of the information is analogous in FEP 2.1.09.21.0A (Transport of Particles Larger than Colloids in EBS), with the exception that the process occurs in an unsaturated environment in this FEP and in a saturated environment in FEP 2.1.09.21.0B. This difference does not affect the evaluation outcome that the above information is appropriate for intended use. The description and qualification used for this data in FEP 2.1.09.21.0B are identically applicable to this FEP. Therefore, the use of the data and information from the report by Reimus (1995 [DIRS 144604], Section 3.2) is qualified for the intended use within this FEP.

J26. FEP 2.1.09.21.0B – TRANSPORT OF PARTICLES LARGER THAN COLLOIDS IN THE SZ

This FEP uses data from the following reference as direct input:

Reimus, P.W. 1995. *Transport of Synthetic Colloids Through Single Saturated Fractures: A Literature Review.* LA-12707-MS. Los Alamos, New Mexico: Los Alamos National Laboratory. ACC: MOL.19950302.0063. [DIRS 144604]

The data from this reference to be qualified for intended use within this FEP support the statement that:

> Inorganic particles larger than 1 μm will settle much more rapidly than they diffuse (Reimus 1995 [DIRS 144604], Section 3.2).

Specifically, the data concern the equations and related discussion on the forces and velocities that dictate particle movement in a viscous fluid. These data are presented in Sections 3.2 and 3.3 of the report by Reimus (1995 [DIRS 144604]), including the subsections. Supporting equations and justification for use include:

- Gravity Force (F_g) and Velocity (V_g) – acting toward surface (Reimus 1995 [DIRS 144604], Section 3.2.1).
- Hydrodynamic Drag Force (F_H) and Velocity (V_H) – acting away from surface (Reimus 1995 [DIRS 144604], Section 3.3.6).
- Diffusion Force (F_d) and Characteristic Diffusion Velocity (V_d) – can act in both directions, but assumed to act away from surface (Reimus 1995 [DIRS 144604], Section 3.2.1).

J26.1 QUALIFICATION METHOD

The method of qualification for the data from Reimus (1995 [DIRS 144604]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it is appropriate considering the extent of documentation present for evaluation of methods. The technical assessment was based on the determination that confidence in the data acquisition or developmental results was warranted. Process attributes used in the qualification of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data/information demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).
- Prior uses of the data/information and associated verification processes (#7).

J26.2 TECHNICAL ASSESSMENT

To demonstrate that the particles larger than colloids will not be transported over long distances, forces acting upon particles moving in viscous fluid in fractures were evaluated as part of the exclusion justification for FEP 2.1.09.21.0B (Transport of Particles Larger than Colloids in the SZ). The primary forces considered are the gravitational force, hydrodynamic drag force, and the diffusion force. The equations describing these forces, as well as the associated velocities of particles acted upon by these forces, were obtained from the following literature review by Reimus (1995 [DIRS 144604]).

The report listed above presents a review of the literature pertaining to colloid transport in single saturated fractures. The arguments are supported with references to physical laws and fundamental science compiled from numerous external publications. The literature review revealed that the dominant forces acting upon particles larger than colloids are body forces such as gravity and fluid drag. These body forces greatly influence a large particle's fluid transport behavior, rather than forces generally associated with molecules (e.g., Van der Waals forces). The equations describing particle transport and associated phenomena were obtained primarily from Section 3.2 of the reference (Colloid Transport by Convection, Diffusion and Force Fields) and Section 3.3 (Colloid Interactions with Surfaces)

The derivation of these equations is appropriately described with adequate references to external literature. Technical reviews of the report by Reimus (1995 [DIRS 144604]) were conducted in 1993 by scientific peers (LANL 1994 [DIRS 185000]; LANL 1993 [DIRS 185002]). The reviews offered confidence that information presented in the report was technically correct and adequate for use. In addition to review records, all of the external references used in the report by Reimus (1995 [DIRS 144604]) are available.

J26.3 DATA QUALIFIED FOR INTENDED USE

Based on the assessment made above, equation and related technical information pertaining to the transport of particles larger than colloids in the saturated zone, from the report by Reimus (1995 [DIRS 144604]), is qualified and appropriate for intended use within FEP 2.1.09.21.0B (Transport of Particles Larger than Colloids in the SZ).

J27. FEP 2.1.09.21.0C – TRANSPORT OF PARTICLES LARGER THAN COLLOIDS IN THE UZ

This FEP uses information from the following reference as direct input:

Reimus, P.W. 1995. *Transport of Synthetic Colloids Through Single Saturated Fractures: A Literature Review.* LA-12707-MS. Los Alamos, New Mexico: Los Alamos National Laboratory. ACC: MOL.19950302.0063. [DIRS 144604]

> The data to be qualified for intended use, obtained from the report by Reimus (1995 [DIRS 144604], Sections 3.2 and 3.3), supports the statement that inorganic particles larger than 1 μm will settle much more rapidly than they diffuse.

Description, justification of the equations, and qualification of the data pertaining to the behavior of small particles transported through fractures in the saturated zone is presented in this appendix under the discussion for FEP 2.1.09.21.0B (Transport of Particles Larger than Colloids in the SZ). The use of the information is analogous in FEP 2.1.09.21.0C (Transport of Particles Larger than Colloids in UZ), with the exception that the process occurs in an unsaturated environment in this FEP and in a saturated environment in FEP 2.1.09.21.0B. This difference does not affect the evaluation outcome that the above information is appropriate for intended use. The description and qualification of these data in FEP 2.1.09.21.0B are identically applicable to this FEP. Therefore, the use of the data and information from the report by Reimus (1995 [DIRS 144604], Section 3.2) is appropriate for FEP 2.1.09.21.0C.

J28. FEP 2.1.11.03.0A – EXOTHERMIC REACTIONS IN THE EBS

This FEP uses input from the following report as direct input:

Garvin, L.J. 2002. *Multi-Canister Overpack Topical Report.* HNF-SD-SNF-SARR-005, Rev. 3. Richland, Washington: Fluor Hanford. ACC: MOL.20040510.0106. [DIRS 169141]

The data to be qualified for intended use within this FEP include:

> The maximum water in a sealed MCO is 4.64 kg (bound in particulate), with less than 200 g being present as free water (Garvin 2002 [DIRS 169141], Table 4-4).
>
> 1.1×10^7 g U-metal per waste package, assuming that the waste package contains two MCOs and each MCO contains Mark IV fuel (3,804 kg U) and scrap (1,832 kg U) for a total of 5,636 kg U (Garvin 2002 [DIRS 169141], Table 4-4).

These data are used to support the calculation showing that only a very small fraction (0.5%) of the fuel in the waste package would be oxidized even if both MCOs in a co-disposal package are each assumed to contain 4.64 kg water, and it is also assumed that all the oxygen in this water is available as free oxygen to convert uranium metal to UO_2 in a rapid exothermic reaction.

The data used in FEP 2.1.11.03.0A (Exothermic Reactions in the EBS) obtained from the report by Garvin (2002 [DIRS 169141]) are the same as the data qualified for the intended use in FEP 2.1.02.08.0A (Pyrophoricity from DSNF). These data were qualified for the use within FEP 2.1.02.08.0A by using the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5), with consideration of the applicable elements of the Spent Nuclear Fuel Project QA program at the organization generating the data (Garvin 2002 [DIRS 169141], Section 13.0). The technical assessment included determination that the employed methodology was acceptable, determination that confidence in the data acquisition or development was warranted, and confirmation that the data had been used in similar applications. The evaluation of the qualification of personnel generating the data, quality and reliability of the measurement control program, adequacy of the QA program, and the evidence of independent audits is presented in the documentation of qualification of data from the same report for FEP 2.1.13.01.0A (Radiolysis). It was concluded that the acceptance criteria for these attributes were met. Meeting of these criteria is also adequate for qualification of these data for their intended use in excluded FEP 2.1.11.03.0A (Exothermic Reactions in the EBS).

J29. FEP 2.1.11.10.0A – THERMAL EFFECTS ON TRANSPORT IN EBS

This FEP uses direct input data from the following journal articles and text book:

The Soret Effect: A Review of Recent Experimental Results (Platten 2006 [DIRS 183864])

Why Molecules Move Along a Temperature Gradient (Duhr and Braun 2006 [DIRS 183865])

Transport Phenomena (Bird et al. 1960 [DIRS 103524]).

J29.1 QUALIFICATION OF DATA FROM PLATTEN 2006

Platten, J.K. 2006. "The Soret Effect: A Review of Recent Experimental Results." *Journal of Applied Mechanics, 73,* 5-15. New York, New York: American Society of Mechanical Engineers. TIC: 259838. [DIRS 183864]

The following data from the above reference are used in FEP 2.1.11.10.0A:

> Typical Soret coefficients for aqueous solutions are on the order of 0.001 to 0.01 K^{-1} (Platen 2006 [DIRS 183864], p. 5).

These data are used in calculations that compare the relative contribution of thermally-driven solute transport to the overall diffusive solute transport mechanism in the EBS.

J29.1.1 Qualification Method

The method of qualification for intended use of the data from Platten (2006 [DIRS 183864]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). Corroborating data are available for comparison with the unqualified data set and any inferences drawn to corroborate the unqualified data can be clearly identified, justified, and documented. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Extent to which the data demonstrate the properties of interest (#3).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J29.1.2 Corroborating Data

To qualify the data from Platten (2006 [DIRS 183864]), Soret coefficient data from other sources are compared to those given by this author in order to establish the magnitude of variation of this parameter for solute transport in various types of liquids. The work by Platten (2006 [DIRS 183864]) focuses on binary liquid mixtures, but it provides comparisons of Soret coefficients obtained from other studies for the same type of liquids, indicating good agreement between values. The range of values for Soret coefficient data given by Platten (2006 [DIRS 183864], Tables 2 through 5) are corroborated with those given by Snowdon and Turner (1960 [DIRS 183867], Table 1), Thornton and Seyfried (1983 [DIRS 183866], Table 1), and Petit et al. (1986 [DIRS 183863], Table II). Although these studies were conducted on various

types of liquids (i.e., electrolytes and binary solutions), the obtained Soret coefficients at steady-state are in the order of 10^{-3} to 10^{-2} 1/K depending on the type of solution. This range in Soret coefficients is also in reasonable agreement with that given by de Groot and Mazur (1962 [DIRS 118615], p. 279) in the order of 10^{-5} to 10^{-3} 1/K encompassing mixed liquids and gases; the lower end of the range in Soret coefficients from this reference is attributed to the gases. Sufficient confidence exists due to the overlap in the range specific to aqueous solutions from the various corroborating sources. Thus, the range specified on the order of 0.001 to 0.01 K^{-1} from Platen (2006 [DIRS 183864], p. 5) is adequate for the intended use within this FEP.

Within the scope of this criterion, added confidence in the data is given by their qualification process attributes, as discussed below and outlined in Attachment 4 of SCI-PRO-001.

Extent to Which the Data Demonstrate the Properties of Interest—The range of values for Soret coefficients given by Platten (2006 [DIRS 183864]) provides a general baseline to evaluate the effects of thermal diffusion, for example, in the invert region. Given the temperature gradient (~5°C) for this domain, this translates into a relatively small contribution to the overall diffusive transport mechanism considering the adopted uncertainty for the invert diffusion coefficient (SNL 2007 [DIRS 177407], Figure 6.3-4).

Extent and Quality of Corroborating Data or Confirmatory Testing Results—The large majority of Soret coefficient data given by Snowdon and Turner (1960 [DIRS 183867], Table 1), Thornton and Seyfried (1983 [DIRS 183866], Table 1), and Petit et al. (1986 [DIRS 183863], Table II) are within the range used in the FEP evaluation, therefore validating their intended use.

J29.1.3 Data Qualified for Intended Use

Based on the extent to which the Soret coefficient data demonstrate the properties of interest and the existence of corroborating data for the range used in the evaluation of thermal diffusion in the FEP, the Soret coefficient data from Platten (2006 [DIRS 183864]) are appropriate and are qualified for use in the screening justification for FEP 2.1.11.10.0A (Thermal Effects on Transport in EBS).

J29.2 JUSTIFICATION OF EQUATION FROM DUHR AND BRAUN 2006

Duhr, S. and Braun, D. 2006. "Why Molecules Move Along a Temperature Gradient." *Proceedings of the National Academy of Sciences of the United States of America, 103,* (52), 19678-19682. Washington, D.C.: National Academy of Sciences. TIC: 259839. [DIRS 183865]

The following technical information and equations are used in FEP 2.1.11.10.0A:

- The Soret effect refers to the development of a concentration gradient in response to a temperature gradient. The magnitude of the effect is described by the Soret coefficient (S_T) (Duhr and Braun 2006 [DIRS 183865], p. 19678): $S_T\ (K^{-1}) = D_T/D$, where D_T is the thermodiffusion coefficient, and D is the diffusion coefficient.

- Because of thermodiffusion, a concentration gradient will develop in response to the temperature gradient, as described by (Duhr and Braun 2006 [DIRS 183865], p. 19,678): $c / c_o = \exp\left[- S_T \left(T - T_o\right)\right]$, where the concentration c is normalized to the concentration c_o at temperature T_o.

These relationships are used in calculations that compare the relative contribution of thermally driven solute transport to the overall diffusive solute transport mechanism in the EBS.

The equation given by Duhr and Braun (2006 [DIRS 183865]) provides the fundamental theoretical representation of the Soret effect. In most aqueous solutions, ions diffuse preferentially in the direction of the thermal gradient; that is, from hot to cold regions. This effect depends mainly on the magnitude of the Soret coefficient (S_T) and the temperature gradient. This formulation is widely used in the theoretical description of thermodiffusion in gases and liquids.

To demonstrate that the equation described above is appropriate for intended use, it was corroborated with the one used by Thornton and Seyfried (1983 [DIRS 183866]) to quantify transport by thermal diffusion in pelagic clay. The equation for the Soret effect has also been rigorously described in the classic text by de Groot and Mazur (1962 [DIRS 118615]) on non-equilibrium thermodynamics.

The equation presented by Duhr and Braun (2006 [DIRS 183865]) for thermal diffusion is corroborated here by direct comparison to representations in slightly different form by other authors. The equation given by Duhr and Braun (2006 [DIRS 183865]) for transport of a unary phase by thermal diffusion at steady-state conditions is expressed as:

$$c / c_o = \exp\left[- S_T \left(T - T_o\right)\right] \qquad \text{(Eq. J29-1)}$$

where c is the concentration of the solute at a temperature T (in degrees Kelvin) and c_o refers to the solute concentration at a some reference temperature T_o. S_T denotes the Soret coefficient and is conventionally defined in the classic text on irreversible thermodynamics by de Groot and Mazur (1962 [DIRS 118615]) as $\frac{D_T}{D}$ where D_T stands for the thermal diffusion coefficient and D corresponds to the chemical diffusion coefficient related to Fickian transport. The Soret effect is used to describe thermal diffusion which relates to the transport of molecules in response to temperature gradients (de Groot and Mazur 1962 [DIRS 118615]; Duhr and Braun 2006 [DIRS 183865]). For many liquids and gases, the Soret coefficient (S_T) is a positive quantity expressed in units of 1/T where T is temperature. Equation J29-1 can be corroborated with that given by other authors for transport by thermal diffusion. Thornton and Seyfried (1983 [DIRS 183866]) describe transport of chemical species by thermal diffusion in experiments where fluids are exposed to a thermal gradient. Their paper use the following formulation to defined the total flux as a result of chemical and thermal diffusion (Thornton and Seyfried 1983 [DIRS 183866]):

$$F = -D\left(\frac{dC}{dz} + S_T c \frac{dT}{dz}\right) + R \qquad \text{(Eq. J29-2)}$$

In the above equation, F stands for the total flux, D refers to the chemical diffusion coefficient, c corresponds to the solute concentration, T denotes temperature, z delineates distance, and R represents the flux component resulting from water–rock interactions. Assuming a steady state condition ($F = 0; R = 0$), Equation J29-2 can be rearranged and recasted as:

$$\frac{dc}{c} = -S_T dT \qquad \text{(Eq. J29-3)}$$

Integrating both sides of Equation J29-3 in the limits of c and c_o for the solute concentration, and similarly T and T_o for temperature, one obtains:

$$\ln(c / c_o) = -S_T (T - T_o) \qquad \text{(Eq. J29-4a)}$$

or

$$c / c_o = \exp\left[-S_T (T - T_o)\right] \qquad \text{(Eq. J29-4b)}$$

Corroboration is confirmed by comparing the identical forms of Equations J29-1 and J29-4b. The same result is obtained for a single component by using Equation 237 of de Groot and Mazur (1962 [DIRS 118615], p. 278) along with the rearrangements and manipulations used in Equations J29-3 through J29-4b. The source reference by de Groot and Mazur (1962 [DIRS 118615]) is considered a classic textbook on non-equilibrium thermodynamics and many subsequent studies on Soret coefficients and transport by thermal diffusion makes reference to this treatise.

Based on the evaluation presented above, the formulation of Soret effect presented by Duhr and Braun (2006 [DIRS 183865]) is justified for intended use within FEP 2.1.11.10.0A (Thermal Effects on Transport in EBS).

J29.3 QUALIFICATION OF DATA FROM BIRD 1960

Bird, R.B.; Stewart, W.E.; and Lightfoot, E.N. 1960. *Transport Phenomena.* New York, New York: John Wiley & Sons. TIC: 208957. [DIRS 103524]

The information to be qualified for intended use within this FEP include:

> According to Bird et al. (1960 [DIRS 103524], pp. 565 to 567), "The thermal diffusion term (Soret effect) describes the tendency for species to diffuse under the influence of a temperature gradient; this effect is quite small."

J29.3.1 Qualification Method

The method of qualification for intended use of the data from the report by Bird et al. (1960 [DIRS 103524]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2) in accordance with SCI-PRO-005, Section 3. The rationale for using this method is that it was the most suitable considering the data and their intended use, and availability of corroborating data. Qualification process attributes used in the data qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).
- Extent and quality of corroborating data or confirmatory testing results (#10).

J29.3.2 Technical Assessment

The technical information on the small effect of thermal diffusion are corroborated by Hirschfelder et al. (1964 [DIRS 171800], p. 8), who state: "Diffusion may also result from a temperature gradient (thermal diffusion or the Soret effect), and the transfer of energy may also result from a concentration gradient (diffusion thermo or Dufour effect). These are small effects." The Soret effect (a coupled Onsager process) is negligible when compared to direct Onsager processes, as discussed in report by Hardin and Chesnut (1997 [DIRS 100534], Section 5, p. 5-1). This report, the authors state: "Many of the Onsager-type coupled processes are probably not significant to repository performance because the required potential gradients are nonexistent or the effects are overwhelmed by direct processes such as Darcy flow, Fickian diffusion, and electrical conduction."

The principal author of the textbook, R. Byron Bird, is a Professor Emeritus of Chemical and Biological Engineering at the University of Wisconsin-Madison. He is a member of the National Academy of Engineering and holds numerous awards and honors for his technical work. He has published numerous books and articles on the topics of transport phenomena, polymer fluid dynamics, polymer kinetic theory, and rheology. *Transport Phenomena* by Bird et al. (1960 [DIRS 103524]), with a second edition released in 2002, has been in print for nearly 50 years and is used widely by the scientific and engineering community. His co-authors, Warren E. Stewart (deceased) and Edwin N. Lightfoot, are also members of the NAE and Professors Emeritus at the University of Wisconsin-Madison. The qualifications of the authors of the publication (Bird et al. 1960 [DIRS 103524]) are considered excellent and the resulting information, specifically the magnitude of the Soret effect for thermal diffusion, is therefore considered adequate.

This source is referenced by multiple handbooks, specifically those by Cho et al. (1998 [DIRS 160802]) and Perry et al. (1984 [DIRS 125806]). These are handbooks in the subject areas of heat transfer and chemical engineering, and thus are widely used in the standard work practices on these topics. The extent to which this source of information addresses the Soret effect for thermal diffusion is adequate and accurate for the intended use within this FEP.

J29.3.3 Data Qualified for Intended Use

Based on the discussion above, the data obtained from the textbook by Bird et al. (1960 [DIRS 103524]) regarding the magnitude of Soret effect are appropriate and considered qualified for intended use within FEP 2.1.11.10.0A (Thermal Effects on Transport in EBS).

J30. FEP 2.1.12.02.0A – GAS GENERATION (HE) FROM WASTE FORM DECAY

This FEP uses data from the following report as direct input:

Piron, J.P. and Pelletier, M. 2001. "State of the Art on the Helium Issues." Section 5.3 of *Synthesis on the Long Term Behavior of the Spent Nuclear Fuel.* Poinssot, C., ed. CEA-R-5958(E). Volume 1. Paris, France: Commissariat à l'Énergie Atomique. TIC: 253976. [DIRS 165318]

The data to be qualified for intended use within this FEP include:

> The decay helium gas pressure is 90 bars at 20°C for a commercial SNF rod with a gap volume of 13 cm^3 and a burnup of 47.5 GWd/MTU after 10,000 years (Piron and Pelletier 2001 [DIRS 165318], Section 5.3.2.4.1).

These data are used to estimate the pressure increase at 50°C in the void volume of a commercial SNF waste package that would occur if all of the He gas generated as a result of alpha particle decay were to be released after 10,000 years.

J30.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from the report by Piron and Pelletier (2001 [DIRS 165318]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2), in accordance with SCI-PRO-005, Section 3. The rationale for using this method is that it was the most suitable considering the data, and their intended use, and availability of corroborating data. Qualification process attributes used in the data qualification were selected from the list provided in Attachment 4 of SCI-PRO-001.

The attribute specifically applicable to these data is the extent and quality of corroborating data (#10).

J30.2 CORROBORATING DATA

The corroborating data used are decay helium inventory and actinide radionuclide inventory data at 1,000 years for spent nuclear fuel rods with a burnup of 45 GWd/MTU (Guenther et al. 1991 [DIRS 109207], p. D.78).

Description of Qualification Approach and Results—The approach is to use the corroborating data to independently calculate the pressure increase at 50°C in the void volume of a commercial SNF waste package that would occur if the He gas generated as a result of alpha particle decay were to be released after 10,000 years.

The steps involved in this calculation are:

- Listing the inventories of decay helium and principal alpha-emitting radionuclides (^{241}Am, ^{240}Pu, ^{239}Pu, and ^{243}Am) in commercial SNF at 1,000 years (Guenther et al. 1991 [DIRS 109207], p. D.78).

- Estimating the change in the helium inventory that will result from alpha decay during the period between 1,000 years and 10,000 years and adding this change to the 1,000 year helium inventory.

- Calculating the pressure increase at 50°C in the void volume of a commercial SNF waste package that would be associated with release of the He gas generated as a result of alpha particle decay at 10,000 years.

The results of data comparison are shown in Table J30-1.

Table J30-1. Nuclide Inventories at 1,000 years and Calculated Helium Inventory Change Due to Decay between 1,000 and 10,000 years

Nuclide	Half Life (years)	Inventory at 1,000 years (g/gU)	Decay Product	Decay Product's Half-Life	Helium Inventory Change (g/gU)
^{4}He		3.89×10^{-5}			
^{241}Am	432.7	3.49×10^{-5}	^{237}Np	2.16×10^{6} years	5.79×10^{-6}
^{240}Pu	6.56×10^{3}	2.58×10^{-3}	^{236}U	2.342×10^{7} years	2.65×10^{-5}
^{239}Pu	2.410×10^{4}	4.99×10^{-3}	^{235}U	7.04×10^{8} years	1.90×10^{-5}
^{243}Am	7.37×10^{3}	2.26×10^{-5}	^{239}Np	2.355 days	2.12×10^{-6}

The third column in Table J30-1 lists the inventories of decay helium and the principal alpha-emitting radionuclides at 1,000 years in commercial SNF with a burnup of 45 GWd/MTU (Guenther et al. 1991 [DIRS 109207], p. D.78). As shown by the decay data summarized in columns 2, 4, and 5 of Table J30-1 (SNL 2007 [DIRS 177424], Tables 4-3 and 4-4), ^{241}Am, ^{240}Pu, and ^{239}Pu decay by alpha particle emission to produce long-lived decay products. The half-lives of these decay products are sufficiently long that decay of the decay product inventory produced from decay of the parent in the interval between 1,000 and 10,000 years does not contribute significantly to the total helium inventory at 10,000 years. The number of helium atoms generated by decay of these radionuclides between 1,000 and 10,000 years is therefore given by the number of decays of the parent nuclide, which is given by: $N_{1000}(1\text{-}e^{-\lambda t})$, where N_{1000} is the number of parent atoms at 1,000 years, λ is the decay constant of the parent atom, and t is the decay time (9,000 years in this case). Because ^{243}Am decays to short-lived ^{239}Np (2.355 days), which then decays by beta particle emission to ^{239}Pu, the helium produced by both the decay of ^{243}Am and ^{239}Pu needs to be considered.

Using the approach described above, the last column in Table J30-1 shows the calculated changes in the helium inventory due to decay of ^{241}Am, ^{240}Pu, ^{239}Pu, and ^{243}Am between 1,000 and 10,000 years (note: because ^{243}Am decay contributes less than 4% of this inventory, the additional contribution from the ^{239}Pu produced in its decay is small and has not been included here). When this helium is added to the 1,000-year helium inventory (Table J30-1, column 3 ^{4}He), the decay helium inventory at 10,000 years is 9.2×10^{-5} g He/g U. Because the average uranium metal content of a commercial SNF waste package is 7.92E6 g (SNL 2007 [DIRS 180472], Table 7-1[a]), the total decay helium in a commercial SNF waste package with average burnup of 45 GWd/MTU is given by: 9.2×10^{-5} g He/g U $\times$ 7.92×10^{6} g U = 7.3×10^{2} g helium, which corresponds to 4.1×10^{3} liters at standard temperature and pressure (7.3×10^{2} g

He / 4 g He/mol × 22.4 liters/mol at STP (rounded and unit conversion from Weast 1985 [DIRS 111561], B-99 and p. F-195). If this helium were released into the 4,737 liter void space of the waste package (SNL 2007 [DIRS 180506], Table 6-3[a]), the resulting pressure increase at 50°C is calculated to be about 1.02 atm using the ideal gas law. (From Boyle's law, $p_1V_1 = p_2V_2$, release of 4.1E3 liters of gas into 4,737 liters of void space of a waste package would cause a pressure increase of $p_2 = 1$ atm × 4.1 × 10^3 L/4,737 L = 0.865 atm at 0°C (273 K). From Gay-Lussac's law, $p_1T_2 = p_2T_1$, the pressure at 50°C (323 K) would be $p_2 = 0.865$ atm × 323 K/273 K = 1.02 atm.)

The results show that the estimated 50°C pressure increase in the waste package void volume that would result from release of the decay helium at 10,000 years is 1.02 atm (~1.03 bar). This result corroborates the conclusion in FEP 2.1.2.12.02.0A (Gas Generation (He) From Waste Form Decay) reached using the data being qualified that the pressure increase at 50°C "would be less than 1.2 bar."

J30.3 DATA QUALIFIED FOR INTENDED USE

The evaluation of the data presented above provides sufficient confidence that data from Piron and Pelletier (2001 [DIRS 165318], Section 5.3.2.4.1) are adequate and are qualified for intended use in the screening justification for FEP 2.1.12.02.0A (Gas Generation (He) From Waste Form Decay).

J31. FEP 2.1.13.01.0A – RADIOLYSIS

This FEP uses direct input data from the following references:

FAI/99-14, Rev. 1, Hydrogen Combustion in an MCO During Interim Storage (Plys and Duncan 1999 [DIRS 184687])

Multi-Canister Overpack Topical Report (Garvin 2002 [DIRS 169141])

Kinetics of the Reduction of $Pu(V)O_2^+$ by Hydrogen Peroxide (Morgenstern and Choppin 1999 [DIRS 184023])

Particulate and Water in Multi-Canister Overpacks (Sexton 2007 [DIRS 184742])

The Effects of Gamma Radiation on the Corrosion of Candidate Materials for the Fabrication of Nuclear Waste Packages (Shoesmith and King 1998 [DIRS 112178]).

J31.1 QUALIFICATION OF DATA FROM PLYS AND DUNCAN 1999

Plys, M.G. and Duncan, D.R. 1999. *FAI/99-14, Rev. 1, Hydrogen Combustion in an MCO During Interim Storage.* SNF-3951, Rev. 0. Richland, Washington: Duke Engineering & Services Hanford. ACC: LLR.20080115.0173. [DIRS 184687]

The data to be qualified for intended use within this FEP include:

> The maximum achievable temperatures and pressures (11 times the initial pressure) for a hydrogen fire in a mixture of oxygen (21%) and helium (79%) inside an MCO is given by Plys and Duncan (1999 [DIRS 184687], Figure 5-1, pp. 6 and 7).

Data Use—The maximum achievable pressure as a result of a hydrogen fire in an MCO is used in excluded FEP 2.1.13.01.0A (Radiolysis) to show that a hydrogen fire involving radiolytic hydrogen is not expected to rupture the waste package.

J31.1.1 Qualification Method

The method of qualification for intended use of the data from the report by Plys and Duncan (1999 [DIRS 184687]) specified above is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was appropriate considering the data to be qualified, the extent of available information on the data, and the personnel that developed the data. The technical assessment was based on the determination that confidence in the data acquisition or developmental results was warranted. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).
- The extent to which the data demonstrate the properties of interest (#3).

- The degree to which independent audits of the process that generated the data were conducted (#11).

J31.1.2 Technical Assessment

The confidence in the data acquisition or developmental results was achieved by considering the following attributes:

Qualifications of Personnel or Organizations Generating the Data—Dr. Martin G. Plys, who developed these data, is a recognized expert in modeling the behavior of flammable gas mixtures. He holds a Sc.D. in Nuclear Engineering from the Massachusetts Institute of Technology. He participated in a Hanford flammable gas elicitation study for, and authorship of, the SCOPE analysis tool. He has experience in chemical reaction, flammability, and heat transfer modeling for several Hanford facilities. He has extensive experience in the analysis of hydrogen combustion in severe reactor accidents and has contributed to development and validation of the Modular Accident Analysis Program (MAAP) nuclear reactor accident analysis models that are used worldwide.

The Extent to Which the Data Demonstrate the Properties of Interest—The adiabatic, isochoric, complete combustion model that was used to calculate the temperatures and pressures that would be associated with hypothetical hydrogen combustion events is described by Plys and Duncan 1999 ([DIRS 184687], Section 5.0 and Appendix A). The approach involves calculating the heat of combustion of an oxygen and helium gas mixture (21% oxygen and 79% helium) with different hydrogen concentrations and then calculating the constant volume temperature and pressure increases assuming that all of the heat of combustion is used to heat up the product gas mixture. The post-event temperatures are calculated using appropriate constant volume heat capacity data for the product gas mixtures and the associated pressures are calculated using the ideal gas law. This approach is appropriate for the intended use of the calculated pressures in FEP 2.1.13.01.0A.

Document Reviews—The source document was reviewed internally by the author's company (Fauke & Associates, Inc.) and also by the Hanford Spent Nuclear Fuel Project (Plys and Duncan 1999 [DIRS 184687], Section 1.0). The calculations were verified by independent review or alternate calculations (Plys and Duncan 1999 [DIRS 184687], Appendix D).

J31.1.3 Data Qualified for Intended Use

The technical assessment presented above provides sufficient confidence that data discussed above, obtained from the report by Plys and Duncan (1999 ([DIRS 184687]), are adequate for intended use and are qualified for use in the screening justification for FEP 2.1.13.01.0A (Radiolysis).

J31.2 QUALIFICATION OF DATA FROM GARVIN 2002

Garvin, L.J. 2002. *Multi-Canister Overpack Topical Report.* HNF-SD-SNF-SARR-005, Rev. 3. Richland, Washington: Fluor Hanford. ACC: MOL.20040510.0106. [DIRS 169141]

The data to be qualified for intended use within this FEP include:

- 6,340 kg uranium metal per MCO (Mark IV maximum fuel load without scrap basket (Garvin 2002 [DIRS 169141], Table 4-4).

- 443 kg zirconium cladding per MCO (Mark IV maximum fuel load without scrap basket (Garvin 2002 [DIRS 169141], Table 4-4).

J31.2.1 Qualification Method

The method of qualification for intended use of the data from the report by Garvin (2002 [DIRS 169141]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The applicable elements of the Spent Nuclear Fuel Project QA program, documented in the source reference (Garvin 2002 [DIRS 169141], Section 13.0) and in the references cited therein were also considered. The rationale for using these methods is that they were appropriate considering the extent of available documentation that allowed the evaluation of the methodology, data acquisition, and data review. The technical assessment included determination that the employed methodology was acceptable, determination that confidence in the data acquisition or development was warranted, and confirmation that the data had been used in similar applications. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).

- The quality and reliability of the measurement control program under which the data were generated (#5).

- The extent to which conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).

- The degree to which independent audits of the process that generated the data were conducted (#11).

J31.2.2 Technical Assessment

The MCO uranium metal mass data and MCO mass of zirconium cladding are used in excluded FEP 2.1.13.01.0A (Radiolysis) to estimate the pressure increase in the void volumes of an MCO and a 2-MCO/2-DHLW waste package that would occur if radiolysis were to convert all of the available water into hydrogen and oxygen.

J31.2.2.1 Data Acquisition Methodology Is Acceptable

The methods used to obtain the MCO fuel materials are described in footnotes “b” and “c” and associated references in the cited data source (Garvin 2002 [DIRS 169141], Table 4-4). The estimates of the U-metal fuel mass loading and cladding were appropriately based on the design basis feed description and the MCO design description. These methods are appropriate.

J31.2.2.2 Confidence in the Data Acquisition or Developmental Results

Confidence in these data is warranted because:

These data and the supporting documents were reviewed and accepted by an independent team of experts (Garvin 2002 [DIRS 169141], Appendix 4C.1 and Attachment 4C-A).

The QA controls under which the work was performed warrant confidence in the results.

The independent review team noted above includes well-recognized experts; their names, together with abridged versions of their qualifications, are provided in the source document (Garvin 2002 [DIRS 169141], Attachment 4C-A). These reviewers examined the consistency and accuracy of the data, appropriateness of the assumptions, the mathematical derivations used, and the consistency with the underlying analytical results and supporting documents and found them to be technically acceptable (Garvin 2002 [DIRS 169141], Appendix 4C.1).

The Spent Nuclear Fuel Project QA program as implemented through *Quality Assurance Program Plan for Implementation of the OCRWM QARD for the Spent Nuclear Fuel Project* (QAPP-OCRWM-001) was designed to satisfy quality assurance requirements "for federal repository acceptance of SNF and satisfy U.S. Nuclear Regulatory Commission equivalency requirements" (Garvin 2002 [DIRS 169141], Section 13.2). This QA program (Garvin 2002 [DIRS 169141], Section 13) was examined using qualification attributes in SCI-PRO-001, Attachment 4:

Qualifications of Personnel or Organizations Generating the Data—The documentation of the Fluor Hanford organization and personnel training and qualifications (Garvin 2002 [DIRS 169141], Sections 13.6.6 and 13.3.2) was reviewed. This review indicates that the requirements for qualifications and training of the personnel who performed this work are comparable to those that would apply to similar work under the YMP.

Quality and Reliability of the Measurement Control Program—The documentation of work process controls (Garvin 2002 [DIRS 169141], Section 13.6.1) was reviewed. This review showed that calibration and maintenance of equipment for data collection were conducted in accordance with approved procedures indicating that appropriate controls were implemented to ensure data quality and reliability.

Conditions under Which the Data Were Generated—As indicated above, the data were generated under *Quality Assurance Program Plan for Implementation of the OCRWM QARD for the Spent Nuclear Fuel Project* (QAPP-OCRWM-001). Because this program implemented the OCRWM QARD requirements, the data were generated under conditions that meet the YMP requirements.

Independent Audits of the Process That Generated the Data—The documentation of independent assessments (including independent audits) of the QA program under which this work was performed (Garvin 2002 [DIRS 169141], Section 13.6.5) was reviewed. This review indicates that the program for independent audits and assessments under which this work was performed was comparable to the YMP program at that time.

In summary, independent review and evaluation of the QA program under which the work was performed warrant confidence in the data.

J31.2.2.3 Data Have Been Used in Similar Applications

The source document *Multi-Canister Overpack Topical Report* (Garvin 2002 [DIRS 169141]) was prepared for the express purpose of describing the MCO design and project-approved parameter values for use in safety analyses for the K Basins Spent Nuclear Fuel Project. These safety analyses were performed under a DOE requirement to achieve "nuclear safety equivalency" to NRC-licensed facilities (Garvin 2002 [DIRS 169141], Section 1.6).

J31.2.3 Data Qualified for Intended Use

The technical assessment presented above provides sufficient confidence that data in the topical report by Garvin (2002 [DIRS 169141]) are adequate and are qualified for intended use in the screening justification for FEP 2.1.13.01.0A (Radiolysis).

J31.3 QUALIFICATION OF DATA FROM MORGENSTERN AND CHOPPIN 1999

Morgenstern, A. and Choppin, G.R. 1999. "Kinetics of the Reduction of $Pu(V)O_2^+$ by Hydrogen Peroxide." *Radiochimica Acta, 36,* 109-113. München, Germany: Oldenbourg Wissenschaftsverlag. TIC: 259871. [DIRS 184023]

The data to be qualified for intended use within this FEP include:

> Reduction of Pu(V) to Pu(IV) in basic solutions having hydrogen peroxide (H_2O_2) concentrations on the order of 0.04 to 0.00001 moles per liter and pH 7.9 to 10.8. (Morgenstern and Choppin 1999 [DIRS 184023], pp. 109 to 111, Table 1).

J31.3.1 Qualification Method

The method of qualification for intended use of the data from the journal article by Morgenstern and Choppin (1999 [DIRS 184023]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2) in accordance with SCI-PRO-005, Section 3. Corroborating data are available for comparison with the unqualified data set and any inferences drawn to corroborate the unqualified data can be clearly identified, justified, and documented. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Extent to which the data demonstrate the properties of interest (#3)
- Extent and quality of corroborating data or confirmatory testing results (#10).

J31.3.2 Corroborating Data

The data by Morgenstern and Choppin (1999 [DIRS 184023]) are unique because most of the existing data on the stability of Pu(IV) in peroxide-rich conditions is for very acidic systems. However, there is corroborative evidence on the reduction of Pu(V) and Pu(VI) and the stability

of Pu(IV) peroxide solids in H_2O_2-rich solutions. One method for precipitating Pu from solution is through the formation of a Pu(IV) peroxide solid (Katz et al. 1986 [DIRS 106312], p. 570). Highly charged Pu(IV)-peroxy complexes forms in relatively dilute acid solutions of H_2O_2 and a precipitate forms with more additions of H_2O_2 (Katz et al. 1986 [DIRS 106312], pp. 704 to 705). This demonstrates that Pu(IV) can be stabilized in the presence of H_2O_2 and is consistent with the reduction kinetics of Pu(V) with respect to H_2O_2 concentration in the experiments by Morgenstern and Choppin (1999 [DIRS 184023]). Given the close behavior in the reduction of Pu(V) and the stability of Pu(IV) in the presence of H_2O_2, this confirms the validity of the observations presented by Morgenstern and Choppin (1999 [DIRS 184023]) for Pu(V) reduction kinetics.

Within the scope of this criterion, added confidence in the data is given by their qualification process attributes as discussed below and outlined in Attachment 4 of SCI-PRO-001:

Extent to Which the Data Demonstrate the Properties of Interest—The data presented by Morgenstern and Choppin (1999 [DIRS 184023]) provide evidence for the reduction of Pu(V) to Pu(IV) in H_2O_2 solutions in the basic pH range. These conditions are more relevant to YMP repository environments where alpha radiolysis can result in the generation of H_2O_2.

Extent and Quality of Corroborating Data or Confirmatory Testing Results—The information presented by Katz et al. (1986 [DIRS 106312]) provides ample evidence for the reduction of Pu(V) and stability of Pu(IV) in H_2O_2-bearing acid solutions. Moreover, it presents details on the formation of Pu(IV)-peroxide solids and their solubilities. The study by Katz et al. (1986 [DIRS 106312]) is considered a reference source of actinide chemistry.

J31.3.3 Data Qualified for Intended Use

Based on the extent to which the data demonstrate the properties of interest and the existence of corroborating data, there is sufficient confidence that the data from Morgenstern and Choppin (1999 [DIRS 184023]) are appropriate and are qualified for intended use in the screening justification for FEP 2.1.13.01.0A (Radiolysis).

J31.4 QUALIFICATION OF DATA FROM SEXTON 2007

Sexton, R.A. 2007. *Particulate and Water in Multi-Canister Overpacks (OCRWM)*. KBC-33403, Rev. 0. Richland, Washington: Fluor Hanford. ACC: LLR.20080116.0003. [DIRS 184742]

The data to be qualified for intended use within this FEP include:

> Maximum amount of free and bound water in an MCO is 4.3 kg (Sexton 2007 [DIRS 184742], Table 2-1).
>
> The average value of free and bound water in an MCO is 1.03 kg (Sexton 2007 [DIRS 184742], Table 2-1).

J31.4.1 Qualification Method

The method of qualification for intended use of data from the report by Sexton (2007 [DIRS 184742]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that that it was appropriate considering the extent of available documentation that allowed the evaluation of the methodology, data acquisition, and data review. The technical assessment included the determination that the employed methodology was acceptable and the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).

- The extent to which conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).

J31.4.2 Technical Assessment

The purpose of this document is to establish a conservative estimate for particulate and bound water in each MCO produced by the NSNFP. Known values along with conservative bounding assumptions were used to determine the estimates for each MCO. The calculated values rely on a number of factors such as adhering particulate, void volume, decay heat, minimum fuel temperature, actual rebound rate and drying conditions. All related sources to the document are clearly identified. A sample calculation is provided to aid in transparency.

The Technical Adequacy of Equipment and Procedures—The methodology is standard practice and generally accepted in the field of science and engineering. The calculations, assumptions and bounding conditions are all well described and provide a level of confidence in the reliability of the data generated. Measurements were well described with a margin of uncertainty to allow a conservative estimate in data to be discerned.

Quality Assurance Program—Although the report does not clearly identify the quality assurance program under which the report was originated, personal communication with NSNFP Manager indicated that the report was generated under the NSNFP QA program. Upon reviewing the NSNFP QA procedure (NSNFP 3.04 Rev. 6) it is permissible not to specify a QA section within certain reports. The report was peer reviewed and approved by NSNFP QA for formal public release as indicated on the engineering document change form. The NSNFP QA program at least partially meets a QA program that supports the YMP license application process or postclosure science.

J31.4.3 Data Qualified for Intended Use

The technical assessment presented above provides sufficient confidence that the data from the report by Sexton (2007 [DIRS 184742]) are appropriate for intended use and are qualified for use in the screening justification for FEP 2.1.13.01.0A (Radiolysis).

J31.5 QUALIFICATION OF DATA FROM SHOESMITH AND KING 1998

Shoesmith, D.W. and King, F. 1998. *The Effects of Gamma Radiation on the Corrosion of Candidate Materials for the Fabrication of Nuclear Waste Packages.* AECL-11999. Pinawa, Manitoba, Canada: Atomic Energy of Canada Limited. ACC: MOL.19990311.0212. [DIRS 112178]

The data to be qualified for intended use within this FEP include:

> At 90°C in Q-Brine (Mg-Cl containing brine), Alloy C-4 corrosion rates are about 0.1 μm/y and 0.05 μm/yr in the absence and presence of about 100 rad/hr gamma radiation, respectively (Shoesmith and King 1998 [DIRS 112178], Table 4). For alloy C-4 tested no enhancement of general corrosion rates and no pitting or crevice corrosion was observed in this dose region (Shoesmith and King 1998 [DIRS 112178], p. 29).
>
> In the dose region 100 rad/hr to 1,000 rad/hr and at 90°C, for Alloy C-4 in Q-Brine (Mg-Cl containing brine) pitting and crevice corrosion is observed (Shoesmith and King 1998 [DIRS 112178], p. 30, Table 4). At higher dose rates (1,000 rad/hr to 100,000 rad/hr) extensive pitting and crevice corrosion is present (Shoesmith and King 1998 [DIRS 112178], p. 30, Table 4).
>
> At 90°C in Q-Brine, Titanium Grade 7 (Ti-7, titanium 99.8-paladium) corrosion rates are about 0.1 μm/yr and 0.7 μm/yr in the absence and presence of 10,000 rad/h gamma radiation, respectively (Shoesmith and King 1998 [DIRS 112178], Table 4). For titanium (Ti-7), passivity is maintained within the dose region, 1,000 rad/hr to 10,000 rad/hr, and at 100,000 rad/hr, although the rate of passive film growth could be an order of magnitude higher than at 1,000 rad/hr (but still only 0.4 μm/yr) (Shoesmith and King 1998 [DIRS 112178], pp. 30 to 31).

J31.5.1 Qualification Method

The method of qualification for intended use of the data from the article by Shoesmith and King (1998 [DIRS 112178]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

J31.5.2 Technical Assessment

The information under consideration reported by Shoesmith and King (1998 [DIRS 112178]) is a summary of the original work done by Smailos and Köster (1987 [DIRS 159774]) entitled "Corrosion Studies on Selected Packaging Materials for Disposal of High Level Wastes" presented as part of the *Materials Reliability in the Back End of the Nuclear Fuel Cycle* proceeding organized by the International Atomic Energy Agency. In some cases, Shoesmith and King (1998 [DIRS 112178]) rely on a summary paper by Smailos et al. (1990 [DIRS 154820]) where the data is in tabular form. Therefore, the focus of the technical assessment will be primarily on the work by Smailos and Köster (1987 [DIRS 159774]). The data collected are appropriately described with test conditions and standard techniques that described corrosion rates and characterization of corrosion pits by Smailos and Köster (1987 [DIRS 159774]) and Smailos et al. (1990 [DIRS 154820]).

The qualifications of personnel generating the data, Smailos and Köster, as well as Shoesmith, are comparable to the qualification of personnel supporting the YMP license application process. Furthermore, the organizations for the authors have programs specifically for the determination of radioactive waste management. For example, Smailos and Köster are from the Institut fur Nukleare Entsorgungstechnik, and Shoesmith from the Department of Chemistry at The University of Western Ontario is relied upon as an expert in corrosion science. King was associated with the Atomic Energy of Canada, Whiteshell Laboratories at the time of the publication.

Q-Brine is a Mg-Cl containing brine ($NaCl$-KCl-$MgCl_2$-$MgSO_4$-H_2O) with the composition of the brine at 55°C containing by weight per cent 1.4% NaCl, 4.7% KCl, 26.8% $MgCl_2$, 1.4% $MgSO_4$, 65.7% H_2O at 55°C (pH = 4.9 at 25°C) (Smailos and Köster 1987 [DIRS 159774], p. 10). Although this brine containing high Mg-Cl content is not relevant at Yucca Mountain, it offers a bounding chemical environment to assess the influence of gamma radiation on relevant material corrosion. The materials studies include Alloy C-4 (similar to Alloy C-22) and Titanium 99.8 Pd (Titanium Grade 7). For comparison to materials that are susceptible to corrosion induced enhancement by radiation, Table 2 of Shoesmith and King (1998 [DIRS 112178]) shows irons, carbon steels, and low alloy steels with corrosion rates ranging from about 20 to 800 μm/y in Q-Brine at 90°C. The corrosion rate for Titanium Grade 7 (Titanium 99.8 Pd ASTM Grade 7) and Alloy C-4 in the absence of gamma radiation is low, and thus these materials are classified as passive materials in Table 4. Even at dose rates as high as about 10,000 rad/hr the corrosion rates for these materials are low, although Alloy C-4 at the higher dose rates has a higher corrosion rate, which may be attributed to localized corrosion.

The corrosion rate for Titanium 99.8-Pd (Titanium Grade 7) over a test period of about 4 years in Q-brine is on the order of 0.1 to 0.2 mm/yr and was not influenced noticeably by test temperatures up to 200°C (Smailos and Köster 1987 [DIRS 159774], Figure 1, p. 13). The influence of gamma radiation (100,000 rad/hr) on Titanium 99.8-Pd corrosion rate in Q-brine was measured as 0.7 μm/yr (Smailos and Köster 1987 [DIRS 159774], p. 18). The assumption that the oxide layer covering the titanium 99.8-Pd sample is TiO_2 is valid, as any contribution by MgO would be small as their densities are very close and the thickness of the oxide layer is relatively small.

Alloy C-4 data are summarized from Smailos et al. 1990 [DIRS 154820], Table 4, where 1 Gy = 100 rad). The data are supported in the study by Smailos and Köster 1987 [DIRS 159774], Sections 3.1 and 3.2, Figures 1 and 8) demonstrating low corrosion rates for alloy C-4 in the absence of gamma radiation and moderate corrosion rates in the presence of gamma radiation. The micrograph in Figure 10 of the report by Smailos and Köster (1987 [DIRS 159774]) shows an example of pitting for Alloy C-4 in Q-Brine at 90°C with gamma radiation 100,000 rad/hr (1,000 Gy/hr).

J31.5.3 Data Qualified for Intended Use

The data from Shoesmith and King (1998 [DIRS 112178], pp. 29 to 31 and Table 4) are appropriate for intended use in the screening justification for FEP 2.1.13.01.0A (Radiolysis). The technical assessment presented above, along with the qualifications of the personnel generating the data, provides sufficient confidence that these data can be considered qualified for intended use within this FEP.

J32. FEP 2.2.06.01.0A – SEISMIC ACTIVITY CHANGES POROSITY AND PERMEABILITY OF ROCK

This FEP uses data from the following report as direct input:

National Research Council 1992. *Ground Water at Yucca Mountain, How High Can It Rise? Final Report of the Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain*. Washington, D.C.: National Academy Press. TIC: 204931. [DIRS 105162]

The data to be qualified for intended use within this FEP include:

> Extension rates declined to 5 to 10 mm/yr at 5 Ma; extension rates are still in a declining state (National Research Council 1992 [DIRS 105162], Chapter 2, p. 24).
>
> Plate tectonic activity has imparted crustal extension stresses within the Basin and Range Province (which includes the Yucca Mountain region) during the past 12 million years. Extension rates between 10 and 12 million years ago ranged between 10 and 30 mm/yr (National Research Council 1992 [DIRS 105162], Chapter 2, p. 22).
>
> Predicted seismic events within the Yucca Mountain region over the next 10,000 years will not alter the large and globally extensive stresses imposed in the rock and in effect over the past 10 to 12 million years (National Research Council 1992 [DIRS 105162], Chapter 5, p. 116).

The intended use of extension rate data and predicted seismic events overlaps with FEP 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults). The effects of seismic activity on hydrologic properties of rocks overlap with FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity). The data used in FEP 1.2.10.01.0A concern water table fluctuation data and are qualified for intended use as a part of data qualification for FEP 2.2.06.01.0A. Specifically, the data used in FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity) are the following:

- Results from the regional stress model approach indicated a maximum water table rise of 50 m (National Research Council 1992 [DIRS 105162], Chapter 5, p. 116).

J32.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from the National Research Council (1992 [DIRS 105162]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

J32.2 TECHNICAL ASSESSMENT

Qualifications of Personnel or Organizations Generating Data—The project that is the subject of this report was approved by the governing board of the National Research Council, whose members are drawn from the councils of the National Academy of Sciences (NAS), the National Academy of Engineering (NAE), and the Institute of Medicine (IOM). The members of the committee responsible for the report were chosen for their special competencies and with regard for appropriate balance. This report has been reviewed by a group other than the authors according to procedures approved by a Report Review Committee consisting of members of the NAS, NAE, and IOM.

The report was published by the National Academies Press (NAP). The NAP was created by the National Academies to publish the reports issued by the NAS, NAE, and IOM, and the Council, all operating under a charter granted by the Congress of the United States. NAP publishes over 200 books a year on a wide range of topics in science, engineering, and health, capturing the most authoritative views on important issues in science and health policy. The institutions represented by NAP are unique in that they attract the nation's leading experts in every field to serve on their blue ribbon panels and committees. The NAS is a private, nonprofit, self-perpetuating society of distinguished scholars engaged in scientific and engineering research and dedicated to the furtherance of science and technology and to their use for the general welfare. Upon the authority of the charter granted to it by the Congress in 1863, the Academy has a mandate that requires it to advise the federal government on scientific and technical matters. The Council was organized by the NAS in 1916 to associate the broad community of science and technology with the Academy's purposes of furthering knowledge and of advising the federal government. Functioning in accordance with general policies determined by the Academy, the Council has become the principal operating agency of both the NAS and the NAE in providing services to the government, the public, and the scientific and engineering communities. The Council is administered jointly by both academies and the IOM.

Data Demonstrate the Properties of Interest— The National Research Council (1992 [DIRS 105162]) reference provides the basis for regional extensional rates declining from a peak of 10 to 30 mm/yr (10-12 Ma) to 5 to 10 mm/yr (5 Ma) and are in a declining state today. The reference also provides a basis for bounding the extent to which the water table may rise or fluctuate in response to future seismic events. Seismic dislocation and water-level changes are discussed in a report prepared by the Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain, commissioned by the National Research Council. The panel reviewed an alternative conceptual model that predicted large changes in groundwater level, and concluded that the model was infeasible. The panel stated that seismic dislocation would at most elevate the water levels a few tens of meters (National Research Council 1992 [DIRS 105162]), p. 7). Alternative perspectives on seismic pumping and water-level changes are discussed in the *Final Environmental Impact Statement* (DOE 2002 [DIRS 155970], p. 3-59), which cites the work by the National Research Council. The panel reviewed the alternative conceptual model and concluded that it was infeasible.

J32.3 DATA QUALIFIED FOR INTENDED USE

Based on the evidence provided above, the data and technical information obtained from the report by the National Research Council (1992 [DIRS 105162]) are appropriate for intended use and are qualified and justified for use in the screening justification for FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock).

J33. FEP 2.2.06.02.0A – SEISMIC ACTIVITY CHANGES POROSITY AND PERMEABILITY OF FAULTS

This FEP uses data from the following report as direct input:

National Research Council 1992. *Ground Water at Yucca Mountain, How High Can It Rise? Final Report of the Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain.* Washington, D.C.: National Academy Press. TIC: 204931. [DIRS 105162]

The data to be qualified for intended use within this FEP include:

> Extension rates declined to 5 to 10 mm/yr at 5 Ma; extension rates are still in a declining state (National Research Council 1992 [DIRS 105162], Chapter 2, p. 24).
>
> Plate tectonic activity has imparted crustal extension stresses within the Basin and Range Province (which includes the Yucca Mountain region) during the past 12 million years. Extension rates between 10 and 12 million years ago ranged between 10 and 30 mm/yr (National Research Council 1992 [DIRS 105162], Chapter 2, p. 22).
>
> Predicted seismic events within the Yucca Mountain region over the next 10,000 years will not alter the large and globally extensive stresses imposed in the rock and in effect over the past 10 to 12 million years (National Research Council 1992 [DIRS 105162], Chapter 5, p. 116).

The intended use of extension rate data and predicted seismic events overlaps with FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock).

J33.1 QUALIFICATION METHOD

The same data obtained from the same reference and used in an analogous context were qualified for intended use in FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock). The data were qualified for intended use using the Technical Assessment method (SCI-PRO-001, Attachment 3, and Method 5). The rationale for using this method is that it was the most suitable considering the data, the data originator, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted and included the consideration of the qualifications of personnel or organizations generating the data and the extent to which the data demonstrate the properties of interest. The same attributes of the data qualification process are applicable to qualifying the data from the National Research Council report (National Research Council 1992 [DIRS 105162]) for the intended use in FEP 2.2.06.01.0A.

J33.2 DATA QUALIFIED FOR INTENDED USE

Based on the evidence provided in this appendix for FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) and the intended use of the data in FEP 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults), the data from the National Research Council (1992 [DIRS 105162]) are appropriate and are qualified for intended use in the screening justification for FEP 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults).

J34. FEP 2.2.06.03.0A – SEISMIC ACTIVITY ALTERS PERCHED WATER ZONES

This FEP uses data from the following report as direct input:

Distribution and Chemistry of Diagenetic Minerals at Yucca Mountain, Nye County, Nevada (Broxton et al. 1987 [DIRS 102004])

Origin, Timing, and Temperature of Secondary Calcite–Silica Mineral Formation at Yucca Mountain, Nevada (Wilson et al. 2003 [DIRS 163589]).

J34.1 QUALIFICATION OF DATA FROM BROXTON 1987

Broxton, D.E.; Bish, D.L.; and Warren, R.G. 1987. "Distribution and Chemistry of Diagenetic Minerals at Yucca Mountain, Nye County, Nevada." *Clays and Clay Minerals, 35,* (2), 89-110. Long Island City, New York: Pergamon Press. TIC: 203900. [DIRS 102004]

The data to be qualified for intended use within this FEP include:

> Most of the zeolitic deposits at Yucca Mountain formed between 11.3 and 13.9 million years ago, and were largely contemporaneous with the most active period of silicic volcanism within the southwest Nevada volcanic field (Broxton et al. 1987 [DIRS 102004], p. 101).

J34.1.1 Data Qualification Method

The method of qualification for intended use of the data from Broxton et al. (1987 [DIRS 102004]) is the Corroborating Data method (SCI-PRO-001, Attachment 3, Method 2). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, their intended use, and the availability of corroborating data. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geologic, mechanical) (#3).
- Extent and quality of corroborating data (#10).

J34.1.2 Technical Assessment and Corroborating Data

The property of interest is related to the intended use of the data where these data are used to support the statement that most of the zeolitic alteration at Yucca Mountain occurred prior to 11.3 million years ago The important feature is that zeolitic alteration occurred millions of years ago. In this regard, corroborating information from additional studies is discussed.

Corroborating information can be found in the report by Bish et al. (1984 [DIRS 106336], p. 72), which states that "[t]extural relations in the samples examined for the present study indicate that substantial zeolitization had already occurred before the geopetal fillings were deposited. This means that zeolitization even in the youngest affected tuff, which corresponds to approximately

12.5 to 13 Myr (Kistler 1968 [DIRS 133347]), was well advanced within about 1.2 to 1.7 Myr after the tuff was deposited." This reference provides confidence that the information from Broxton et al. (1987 [DIRS 102004]) is reliable.

J34.1.3 Data Qualified for Intended Use

Based on the available corroborating data, the information from Broxton et al. (1987 [DIRS 102004], p. 101) is adequate for intended use FEP 2.2.06.03.0A (Seismic activity alters perched water zones) and is considered qualified for intended use within this FEP.

J34.2 QUALIFICATION OF DATA FROM WILSON ET AL. 2003

Wilson, N.S.F.; Cline, J.S.; and Amelin, Y.V. 2003. "Origin, Timing, and Temperature of Secondary Calcite–Silica Mineral Formation at Yucca Mountain, Nevada." *Geochimica et Cosmochimica Acta, 67,* (6), 1145-1176. New York, New York: Pergamon. [DIRS 163589]

The data from this journal article to be qualified for intended use include:

> Studies of secondary minerals at Yucca Mountain using petrography, fluid-inclusion thermometry, and uranium-lead dating indicate that unsaturated-zone temperatures have remained close to the current ambient values over the past 2 to 5 Ma (Wilson et al. 2003 [DIRS 163589], Section 8).

Qualification of the data from Wilson et al. (2003 [DIRS 163589, Section 8) is presented in this appendix under the discussion for FEP 1.2.06.00.0A (Hydrothermal Activity). The intended use of the data is the same as that presented in FEP 1.2.06.00.0A (Hydrothermal Activity) and the qualification used for this data in FEP 1.2.06.00.0A is identically applicable to this FEP. Therefore, the use of the data and information from the report by Wilson (2003 [DIRS 163589], Section 8) is qualified for the intended use within this FEP.

J35. FEP 2.2.07.14.0A – CHEMICALLY-INDUCED DENSITY EFFECTS ON GROUNDWATER FLOW

This FEP uses data from the following report as direct input:

Zhang, H. and Schwartz, F.W. 1995. "Multispecies Contaminant Plumes in Variable Density Flow Systems." *Water Resources Research, 31,* (4), 837-847. Washington, D.C.: American Geophysical Union. TIC: 252318. [DIRS 183479]

The data to be qualified for intended use within this FEP include:

> In order for density effects to be present in the model simulations, the concentration of the leachate (or contaminant plume) had to be at least 2,000 mg/L (which corresponded to a solution density of 999.7 kg/m^3 at 20°C, in a native groundwater with a density of 998.2 kg/m^3 at 20°C; i.e., a density contrast of ~0.15%) in a very dilute native groundwater at 20°C for a specific discharge of ~30 m/yr through a homogeneous isotropic porous medium with a flow porosity of 0.25, yielding a horizontal seepage velocity of ~120 m/yr (Zhang and Schwartz 1995 [DIRS 183479], pp. 839, 840, 843, and 844).

The intended use of the data is to support the expectation that the density contrast between unsaturated zone water entering the saturated zone and saturated zone water is not large enough to cause significant density-driven flow except for possibly during the relatively short pulse associated with the repository thermal pulse.

J35.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from the report by Zhang and Schwartz (1995 [DIRS 183479]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviewers of the data and their results (#8).

J35.2 TECHNICAL ASSESSMENT OF THE DATA

Qualification of Personnel or Organizations Generating the Data—Hubao Zhang and Franklin Schwartz were both at Ohio State University at the time the article was written. The second author, Dr. Schwartz, is a professor in the School of Earth Sciences at Ohio State University and is an Ohio Eminent Scholar. Drs. Zhang and Schwartz are co-authors of the textbook *Fundamentals of Groundwater* released in 2002. Additionally, Dr. Schwartz is co-author of the textbook *Physical and Chemical Hydrogeology* published in 1990. He has numerous awards, including the E.O. Meinzer Award and the Excellence in Science and Engineering Award. In 1992 he was named as a Fellow of the American Geophysical Union.

Extent to Which the Data Demonstrate the Properties of Interest—The simulations presented by Zhang and Schwartz are for the case of a contaminant added to a water table of a flowing groundwater system. They examined several cases to assess the concentration of the contaminant plume required for density-driven sinking to occur. Simulations were conducted with leachate concentrations of 5,000 mg/L, 3,000 mg/L, and 1,000 mg/L. Sinking occurred in the first two cases, and the authors surmise that the cutoff for a sinking plume would occur for concentrations above 2,000 mg/L. These simulations were performed assuming a groundwater density of 998.2 kg/m^3. Regarding the density contrast, the authors state on p. 844 that "As $[Co]_1$ becomes less than about 2,000 mg/L, the density effects become minimal." In Table 1 on p. 838, the density of 2,000 mg/L NaCl is listed as 999.7 kg/m^3. At the bottom of p. 839 it is stated that the density of the ambient groundwater is chosen as 998.2 kg/m^3. Thus, the density contrast is (999.7 – 998.2)/998.2 = 0.0015, or 0.15%. The work of Zhang and Schwartz provides the basis for estimating the concentration of a radionuclide plume necessary to cause density effects on groundwater flow. Thus the data are demonstrated to provide properties of interest.

Peer Review of the Data and Their Results—The data and analysis from Zhang and Schwartz were published in the journal Water Resources Research. Water Resources Research is an interdisciplinary journal integrating research in the social and natural sciences of water. Articles published in Water Resources Research are evaluated through a peer-review process before publication. Therefore, this work has received prior peer review.

J35.3 DATA QUALIFIED FOR INTENDED USE

The above technical evaluation indicates that there is sufficient confidence that the data obtained from the report by Zhang and Schwartz (1995 [DIRS 183479]) are appropriate and are qualified use in the screening justification for FEP 2.2.07.14.0A (Chemically-Induced Density Effects on Groundwater Flow).

J36. FEP 2.2.08.07.0C – RADIONUCLIDE SOLUBILITY LIMITS IN THE BIOSPHERE

This FEP uses direct input from the following report:

Doorenbos, J. and Pruitt, W.O. 1977. *Crop Water Requirements.* FAO Irrigation and Drainage Paper 24. Rome, Italy: Food and Agriculture Organization of the United Nations. TIC: 245199. [DIRS 103062]

> The data from this reference that are being used as direct input are the salinity tolerances for crops (Doorenbos and Pruitt 1977 [DIRS 103062], Table 36, p. 78).

The intended use of these data in FEP 2.2.08.07.0C is to compare the concentration of salts in groundwater with the range of water salinity tolerated by crops without the yield reduction.

J36.1 QUALIFICATION METHOD

The method of qualification for intended use of data from the report by Doorenbos and Pruitt (1977 [DIRS 103062]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was appropriate considering the available information on the data and the originating agency. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification were selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data (#1).
- The extent to which the data demonstrate the properties of interest (#3).

J36.2 TECHNICAL ASSESSMENT

Qualifications of Personnel or Organizations Generating the Data—The data on crop salt tolerance were obtained from the publication by the Food and Agriculture Organization of the United Nations. The methods for calculating net irrigation and seasonal irrigation requirements in the report by Doorenbos and Pruitt (1977 ([DIRS 103062]) and the supporting data are widely accepted.

The Food and Agriculture Organization (FAO) is a specialized agency of the United Nations that leads international efforts to defeat hunger. The FAO not only acts as a neutral forum where all nations meet as equals to negotiate agreements and debate policy, but also is also a source of knowledge and information. The Food and Agriculture Organization serves as a network for sharing knowledge related to sustainable food production. It uses the expertise of its staff and other professionals to collect, analyze, and disseminate data that help development of good agricultural practices. FAO Internet publishes technical documents, hundreds of newsletters, reports and books; distributes several magazines; and creates numerous CD-ROMs. The FAO publication and data can be considered reliable and representative of the current state of knowledge.

The Extent to Which the Data Demonstrate the Properties of Interest—The salt tolerance of individual crops is expressed in terms of electrical conductivity. The data from Doorenbos and Pruitt (1977 [DIRS 103062], Table 36, p. 78) are for crop salt tolerance values with no reduction in yield. The data were available for many common crops that can be grown in Amargosa Valley, including the most common crop, alfalfa, and thus were representative of the local conditions.

J36.3 DATA QUALIFIED FOR INTENDED USE

The above technical evaluation indicates that the qualification attributes were met and there is sufficient confidence that the data from the report by Doorenbos and Pruitt (1977 [DIRS 103062]) are appropriate and are qualified for use in the screening justification for FEP 2.2.08.07.0C (Radionuclide Solubility Limits in the Biosphere).

J37. FEP 2.2.08.11.0A – GROUNDWATER DISCHARGE TO SURFACE WITHIN THE REFERENCE BIOSPHERE

This FEP uses data from the following report as direct input:

Paces, J.B.; Whelan, J.F.; Forester, R.M.; Bradbury, J.P.; Marshall, B.D.; and Mahan, S.A. 1997. *Summary of Discharge Deposits in the Amargosa Valley.* Milestone SPC333M4. Denver, Colorado: U.S. Geological Survey. ACC: MOL.19981104.0151. [DIRS 109148]

The general information to be qualified for intended use within this FEP describes the paleospring deposits located in Crater Flat, Crater Flat Wash, Amargosa Valley Diatomite, Indian Pass, Scranton Well, Mesquite Wash, and the Amargosa River Snail Site (Paces et al. 1997 [DIRS 109148], Figure 18).

The specific data, inclusive to the general information above, that are part of the qualification are the following:

> With the exception of the Amargosa River Snail Site, geochemical dating indicates that the last episode of paleospring activity for the majority of paleosprings occurred between 14,000 to 20,000 years ago, or longer (Paces et al. 1997 [DIRS 109148], Figure 18).
>
> Scranton Wells was active 40,000 to 60,000 years ago Mesquite Wash was active 30,000 years ago, and the Amargosa River Snail Site between 9,000 to 12,000 years ago (Paces et al. 1997 [DIRS 109148], Figure 18).

J37.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Paces et al. (1997 [DIRS 109148]) listed above is the Equivalent QA Program approach (SCI-PRO-001, Attachment 3, Method 1). The rationale for using this method is that it was the most suitable considering the data and available documentation of the QA program. The YMP branch of the USGS had worked in cooperation with the YMP Management and Operating Contractor for many years, and USGS Milestone SPC333M4 (USGS 1997 [DIRS 171970]) activities underwent a DOE Office of Quality Assurance (OQA) surveillance in late 1997. The objective of the surveillance was to verify compliance with USGS technical and implementing procedures in the production of the milestone.

The evaluation criteria are based on the requirements in Attachment 3 and the applicable qualification attributes listed in Attachment 4 of SCI-PRO-001. Use of qualification Method 1, Equivalent QA Program, requires that an initial evaluation of the data quality and correctness be made by comparing the methods used to plan, collect, and analyze the data against generally accepted scientific or engineering practices. If this comparison is adequate, then the acquisition, development, or processing of data must be demonstrated to be functionally equivalent (i.e., similar in scope and implementation) to the general process requirements of *Quality Assurance Requirements and Description* (QARD) (DOE 2007 [DIRS 182051]). A condition of this method is the demonstration of the functional equivalence of the data-gathering process to applicable QARD concepts, as identified by the attributes in SCI-PRO-001, Attachment 4 (e.g., Attributes 1, 2, 5, 6, 8, and/or 11). The attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).

- The quality and reliability of the measurement control program under which the data were generated (#5).

- The extent to which conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).

- Prior peer or other professional reviews of the data and their results (#8).

J37.2 DEMONSTRATION OF EQUIVALENT QA PROGRAM

The report by Paces et al. (1997 [DIRS 109148]) was prepared by the Environmental Science Team, Earth Science Investigations Program, YMP Branch, Water Resources Division of USGS regarding activities conducted in association with Milestone SPC333M4, "Evaluation of Paleo Ground-Water Discharge" (DOE 1997 [DIRS 171970]). This USGS report analyzes age, isotope, and paleontological data and summarizes the current understanding and implications of paleospring deposits located in the Amargosa Valley area.

In the initial evaluation of data quality and correctness, Paces et al. (1997 [DIRS 109148]) analyze the new age, isotope, and paleontological data and present an interpretive evaluation on past discharge activity in the northern Amargosa Valley. Thermoluminescence data, stable isotope data (O and C), other isotope data (strontium and uranium-series disequilibrium), as well as diatom and ostracode (paleontological) data, are generally accepted by the scientific (geologic and hydrologic) community for use in determining age, temperature, climatic, and environmental conditions of paleo flowing springs. Standard geologic field practices were used for sampling from trench wall and natural outcrops, mass spectrometry was used in collecting isotopic data, and thermoluminescence data were collected by a commonly accepted technique. A list of all procedures used for this activity is found in OQA surveillance record No. USGS-SR-97-061 (DOE 1997 [DIRS 171970], Item 8). These technical procedures are all USGS approved. The data quality and correctness are determined to be adequate for the implementation of the Equivalent QA Program qualification method. OQA Surveillance No. USGS-SR-97-061 (DOE 1997 [DIRS 171970]) was conducted to verify compliance with USGS procedures in the preparation of memorandum report Milestone SPC333M4, "Evaluation of Paleo Ground-Water Discharge," September 23 through October 3, 1997. The conclusion of the surveillance was that the USGS has adequately implemented the QA program as it applied to the activities conducted in association with Milestone SPC333M4. No deficiency documents were issued as a result of this surveillance.

The results of assessment of the functional equivalence of the data-gathering process to applicable QARD concepts, as identified by the attributes in Attachment 4 of SCI-PRO-001, are the following:

Qualifications of Personnel or Organizations Generating the Data—Items 1 and 2, and Attachment 1 of Surveillance Record No. USGS-SR-97-061 (DOE 1997 [DIRS 171970]) indicate that the qualifications of personnel generating the data are comparable to those qualifications approved by the 10 CFR 60, Subpart G [DIRS 100015] program.

Technical Adequacy of Equipment and Procedures Used to Collect Data—Items 3, 4, 8, and 10 of the surveillance record (DOE 1997 [DIRS 171970]) demonstrate the technical adequacy of equipment and procedures used to collect and analyze the data.

Quality and Reliability of the Measurement Control Program—Items 3, 4, 5, 6, 7, 8, and 10 of the surveillance record (DOE 1997 [DIRS 171970]) demonstrate the quality and reliability of the measurement control program under which the data were generated.

Conditions under Which the Data Were Generated May Meet QA Program—The surveillance record determined that the USGS has adequately implemented a QA program as it applies to activities associated with Milestone SPC333M4 (DOE 1997 [DIRS 171970]). This conclusion was based on objective evidence and discussions with USGS personnel. There were no deficiency documents issued as a result of the surveillance. The conditions under which the data were generated partially meet 10 CFR 60, Subpart G [DIRS 100015].

Prior Peer or Other Professional Reviews—Item 11 of the surveillance record (DOE 1997 [DIRS 171970]) demonstrates that technical reviews were done before the data packages were sent to the YMP. Dr. Zell Peterman, Chief of the USGS YMP Environmental Science Team, conducted a management review. The evaluation found that supporting information for the data in the USGS report (Paces et al. 1997 [DIRS 109148]) was suitable for the implementation of the Equivalent QA Program qualification method.

The Equivalent QA Program method was used to determine that qualification Attributes 1, 2, 5, 6, and 8 (Attachment 4, SCI-PRO-001) were satisfied by the USGS QA program. The USGS QA program was found to be the functional equivalent to the general processes required by the QARD (DOE 2007 [DIRS 182051]).

J37.3 DATA QUALIFIED FOR INTENDED USE

The data described above were determined to be appropriate for intended use. Based on the result of evaluation of the Qualify Assurance Program, it was concluded that the data from the report by Paces et al. can be considered qualified for intended use within FEP 2.2.08.11.0A (Groundwater Discharge to Surface within the Reference Biosphere).

J38. FEP 2.2.10.11.0A – NATURAL AIR FLOW IN THE UZ

This FEP uses data from the following report as direct input:

Martinez M.J. and Nilson, R.H. 1999. "Estimates of Barometric Pumping of Moisture through Unsaturated Fractured Rock." *Transport in Porous Media, 36,* (1), 85-119. Dordrecht, The Netherlands: Kluwer Academic Publishers. TIC: 257394. [DIRS 174095]

The data to be qualified for intended use within this FEP include:

> Estimates of the rate of water removal from Yucca Mountain through vapor transport range from 0.001 mm/yr to 0.3 mm/yr (Martinez and Nilson 1999 [DIRS 174095], p. 106).

J38.1 QUALIFICATION METHOD

The methods of qualification for intended use of the data from Martinez and Nilson (1999 [DIRS 174095]) are the Corroborating Data and Technical Assessment methods (SCI-PRO-001, Attachment 3, Methods 2 and 5). The rationale for using these methods is that they were the most suitable considering the data, their existing documentation, their intended use, and the availability of corroborating data. The technical assessment was based on the determination that that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (#3).
- Extent and quality of corroborating data (#10).

The qualifications of the personnel generating the above data will be presented and demonstrated to be comparable to qualification requirements for personnel supporting the YMP license application process or postclosure science. Corroborating data will also be presented to show that the data are consistent with data in other published reports.

J38.2 TECHNICAL ASSESSMENT

Qualifications of Personnel Generating the Data—Dr. Mario Martinez was the lead author and developer of the data being qualified. Dr. Martinez received a Ph.D. in Engineering from the University of California at Berkeley (1987) with an emphasis in fluid dynamics. Dr. Martinez has extensive experience in developing and applying multicomponent, multiphase models for flow in heterogeneous porous media, including thermally driven two-phase flows for

heterogeneous fractured geologic media. Dr. Martinez has published over 30 papers in refereed journals and proceedings on multiphase flows, fluid dynamics, porous media, and numerical methods. Dr. Martinez's contribution to the YMP began in 1982 and has continued at various part-time levels to the present. Early work included developing finite element simulations tools for flow and transport modeling, resulting in a number of codes (e.g., FEMTRAN, NORIA and SAGUARO). Dr. Martinez was an early researcher in the relatively new subsurface area of fractured media, resulting in one of the first models describing flow into unsaturated fractures and its dependence on fracture and formation characteristics. Martinez also contributed to research into the effects of barometric pumping at Yucca Mountain. During the mid-1990s Martinez led the development of parallel processing codes for multiphase thermal flows in porous materials, resulting in the code PorSalsa, which has also been used on the YMP.

Technical Adequacy and Extent to Which the Data Demonstrate Properties of Interest—Martinez and Nilson (1999 [DIRS 174095], p. 106) present estimates for the annual net outflow of moisture from depth to the surface in the repository vicinity. In their paper, they develop a rigorous model for moisture transport in the fractures and matrix using first principles. These data are used in this FEP to support the statement that estimated rates of water removed as vapor by natural air flow in Yucca Mountain are negligible in comparison with the estimates for average infiltration at this site, which range from 3 to 73 mm/yr (SNL 2007 [DIRS 184614], Table 6.1-2).

J38.3 CORROBORATING DATA

The control volume model used to predict the theoretical maximum outflow was also presented in the report by Tsang and Pruess (1989 [DIRS 184794]). They present a solution that is consistent with Martinez and Nilson (1999 [DIRS 174095]), yielding a result of 0.3 mm/yr. In addition, Tsang and Pruess (1990 [DIRS 172018]) present gas-phase flow and diffusion studies that estimate the upper limit of gas-phase vapor outflow to be 0.1 mm/yr. Both Drs. Tsang and Pruess are senior scientists at Lawrence Berkeley National Laboratory and have worked on the YMP for over 20 years each. These corroborating data indicate that a theoretical upper limit of 0.3 mm/yr is consistent among multiple researchers on the project.

J38.4 DATA QUALIFIED FOR INTENDED USE

The technical assessment and corroborating data methods presented above, along with the qualifications of the personnel generating the data, provide sufficient confidence that the data from Martinez and Nilson (1999 [DIRS 174095], p. 106) are appropriate and qualified for use in the screening justification for FEP 2.2.10.11.0A (Natural Air Flow in the UZ).

J39. FEP 2.2.10.14.0A – MINERALOGIC DEHYDRATION REACTIONS

This FEP uses data from the following reports as direct input:

Review of the Thermal Stability and Cation Exchange Properties of the Zeolite Minerals Clinoptilolite, Mordenite, and Analcime: Applications to Radioactive Waste Isolation in Silicic Tuff (Smyth and Caporuscio 1981 [DIRS 174060])

Use of Zeolitic Tuff in the Building Industry (Colella et al. 2001 [DIRS 184454]).

J39.1 QUALIFICATION OF DATA FROM SMYTH AND CAPORUSCIO 1981

Smyth, J.R. and Caporuscio, F.A. 1981. *Review of the Thermal Stability and Cation Exchange Properties of the Zeolite Minerals Clinoptilolite, Mordenite, and Analcime: Applications to Radioactive Waste Isolation in Silicic Tuff*. LA-8841-MS. Los Alamos, New Mexico: Los Alamos Scientific Laboratory. ACC: HQS.19880517.2065. [DIRS 184454]

The data from that report to be qualified include:

> Volume and weight changes observed upon heating were recorded for a rock sample from the zeolitized Calico Hills Formation. The tuff was soaked in water at 91°C for 48 hours and then kept at approximately 95°C in a drying oven. The core was weighed and measured at the beginning of the experiment and periodically throughout the 32 hour dry-heating period. The amount of water lost between the highest measured volume (hour 1) and the next measurement (hour 2), relative to the total water lost during heating, was 70.6 wt % calculated as 100 × (19.77033 g – 18.5134 g)/(19.7703 g – 17.9906 g) (Smyth and Caporuscio 1981 [DIRS 174060], Tables A-1 and B-1, sample YM-40).
>
> The selected upper bounding value for volume reduction of initially saturated zeolitic tuff heated in air at 95°C was 0.76 vol % (Smyth and Caporuscio 1981 [DIRS 174060], Table A-1, sample YM-38).

J39.1.1 Qualification Method

The method of qualification of the data obtained from the scientific paper by Smyth and Caporuscio (1981 [DIRS 174060]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- Qualifications of personnel or organizations generating the data are comparable to qualification requirements or personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

J39.1.2 Technical Assessment

Qualification of Personnel or Organizations Generating the Data—Joseph R. Smyth is a professor in the Geological Sciences Department of the University of Colorado at Boulder, where his expertise includes mineral physics. Dr. Smyth has authored or co-authored more than 100 journal articles and refereed reports on the physical properties of minerals. Florie A. Caporuscio is a technical staff member at the Los Alamos National Laboratory with expertise in mineralogy and geochemistry. He earned his B.S. in geology from the University of Massachusetts, his M.S. in geology from Arizona State University, and Ph.D. in geology from the University of Colorado. He served as section chief of the U.S. Environmental Protection Agency's Waste Isolation Pilot Plant (WIPP) Project Technical Review Program.

Extent to Which the Data Demonstrate the Properties of Interest—One of the properties of interest to assess mineralogic dehydration reactions (FEP 2.2.10.14.0A) is the change to the volume and density of the zeolitized tuffs below the repository as the tuffs are heated due to emplacement of radioactive waste in the tunnels and the subsequent cooling as the heat generated by the waste decreases with time. The measurements presented in Appendix A of Smyth and Caporuscio (1981 [DIRS 174060]) are the change in weight and volume of a clinoptilolite-rich core sample of Calico Hills Formation tuff upon hydration, followed by heating at constant temperature. The measurements were performed at temperatures just below 100°C to represent elevated, but non-boiling temperatures to show that weight and volume changes can occur. The measurements presented in Appendix B of Smyth and Caporuscio (1981 [DIRS 174060]) are of density changes in four tuff samples upon heating beginning at 25°C and extending up to 500°C. Except for the first temperature, the temperatures were all above boiling and represent possible conditions near the repository drifts. The data under consideration are used in FEP 2.2.10.14.0A (Mineralogic Dehydration Reactions) to estimate a bounding value for the amount of rock shrinkage due to zeolite hydration that would occur under predicted repository conditions.

J39.1.3 Data Qualified for Intended Use

The data obtained from the report by Smyth and Caporuscio (1981 [DIRS 174060], Appendices A and B) are appropriate for intended use. The above discussion presents adequate confidence that these data can be considered qualified for use in the screening justification for FEP 2.2.10.14.0A (Mineralogic Dehydration Reactions).

J39.2 QUALIFICATION OF DATA FROM COLELLA ET AL. 2001

Colella, C.; de' Gennaro, M.; and Aiello, R. 2001. "Use of Zeolitic Tuff in the Building Industry." *Reviews in Mineralogy and Geochemistry, 45,* 551-587. Washington, D.C.: Mineralogical Society of America. TIC: 259937. [DIRS 184454]

The data to be qualified for intended use within this FEP include:

> Physical changes in zeolitic tuff lead to the possible formation of microcracks. A scanning electron image of such a weathered zeolitic tuff shows microcracks with apertures of about one to two micrometers (Colella et al. 2001 [DIRS 184454], Figure 24).

J39.2.1 Qualification Method

The methods of qualification for intended use of the data obtained from the scientific paper by (Colella et al. 2001 [DIRS 184454]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically relevant to these data are:

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Prior peer or other professional reviews of the data and their results (#8).

J39.2.2 Technical Assessment of Data

Extent to which the Data Demonstrate the Properties of Interest—The work of Colella et al. (2001 [DIRS 184454]) documents the uses of zeolitized tuff as a building material. More importantly, they also present the mechanical and physical properties of zeolitic tuff which include physical decay phenomena. Of particular interest to Yucca Mountain studies are the effects of water sorption and desorption into zeolitic tuff.

One observation (Colella et al. 2001 [DIRS 184454], p. 573, Figure 24) is the important role of water in the decay of zeolitic tuff building materials. The evaporation of water from tuff, particularly water with dissolved salts that crystallize during evaporation, may generate internal stresses resulting in the formation of microcracks. These data in the study by Colella et al. (2001 [DIRS 184454]) demonstrate properties of interest to Yucca Mountain.

Prior Peer or Other Professional Reviews of the Data and their Results—The article by Colella et al. (2001 [DIRS 184454]) was published in the Reviews in Minerology and Geochemistry series, submissions to which are technically reviewed and approved. For example, in the Style Guide for the Reviews in Minerology and Geochemistry series, the role of the volume editor is defined: "[t]he volume editor is responsible for the scientific content of the book and its organization. He/she will edit the authors' contributions to assure high quality of the technical content, clarity and succinctness of presentation of the subject matter, cross-referencing from one chapter to another, quality of figures and tables, indexes, etc." Thus, the work of Colella et al. (2001 [DIRS 184454]) was peer-reviewed by the volume editor prior to publication.

J39.2.3 Data Qualified for Intended Use

The above discussion shows that the data demonstrate the properties of interest and are appropriate for intended use. Based on the results of technical assessment, the data obtained from the scientific journal article by Colella et al. (2001 [DIRS 184454]) are also qualified for use in the screening justification for FEP 2.2.10.14.0A (Mineralogic Dehydration Reactions).

J40. FEP 2.2.11.03.0A – GAS TRANSPORT IN GEOSPHERE

This FEP uses data from the following report as direct input:

DOE 2002. *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada.* DOE/EIS-0250. Washington, D.C.: U.S. Department of Energy, Office of Civilian Radioactive Waste Management. ACC: MOL.20020524.0314; MOL.20020524.0315; MOL.20020524.0316; MOL.20020524.0317; MOL.20020524.0318; MOL.20020524.0319; MOL.20020524.0320. [DIRS 155970]

The data to be qualified include:

> Modeling of potential annual doses from gas-phase geosphere transport of ^{14}C shows that the individual maximum radiological dose is 1.8×10^{-10} mrem/yr, which corresponds to a maximum gas-phase release rate that occurs at 1,700 years following repository closure (DOE 2002 [DIRS 155970], Section I.7).
>
> Based on gas flow studies, radon released from the repository in the gas phase is expected to radioactively decay before reaching the ground surface (DOE 2002 [DIRS 155970], Section I.7.3).

J40.1 QUALIFICATION METHOD

The method of qualification of the data from the DOE report (DOE 2002 [DIRS 155970]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, and Method 5). The rationale for using this method is that it was the most suitable considering the data and the existing documentation regarding the data and the data originator. The technical assessment was based on the determination that that confidence in the data acquisition or development was warranted. Qualification process attributes used in the qualification are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualifications of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (#3).

In this technical assessment, the qualifications of the personnel generating the above data will be presented and demonstrated to be comparable to qualification requirements for personnel supporting the YMP license application process or postclosure science. In addition, the methods used to obtain the data above will be reviewed and evaluated, and a check of the calculations will be performed, where applicable.

J40.2 TECHNICAL ASSESSMENT

Qualifications of Personnel Generating the Data—Dr. Paul Eslinger performed the atmospheric release calculations reported in Appendix I.7 of the source report (DOE 2002 [DIRS 155970]. Dr. Eslinger is a Staff Scientist in the Risk and Decision Sciences Group at Pacific Northwest National Laboratory. He received his Ph.D. in Statistics in 1983 from Southern Methodist University and his M.A. and B.S. in Mathematics. His technical expertise is in statistics, performance estimation for nuclear waste disposal concepts, and risk analysis. Dr. Eslinger led the performance assessment modeling activities for the Environmental Impact Statement for the YMP from 1996 through 2001. The Environmental Impact Statement, prepared for the U.S. Department of Energy and published in 2002, addressed the disposal of commercial spent nuclear fuel and defense high-level radioactive wastes. Dr. Eslinger also led the inventory and performance assessment modeling activities for the second supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant (WIPP) located near Carlsbad, New Mexico. This Environmental Impact Statement, published by the U.S. Department of Energy in 1997, addressed the disposal phase of development of the facility for the long-term disposal of transuranic wastes. Dr. Eslinger was also involved in the Systems Assessment Capability project (1998 through 2006), in which he calculated human, ecological, and economic risk estimates for proposed end-states of the cleanup of the Hanford nuclear reservation. Dr. Eslinger serves as an ad-hoc member of an EPA Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) Scientific Advisory Panel that is examining stochastic risk assessment approaches for investigating ecological effects of pesticides. Dr. Eslinger also served on a validation review team for the U.S. Department of Energy that examined the long-term performance models for a high-level radioactive waste repository.

Technical Adequacy and Extent to Which the Data Demonstrate Properties of Interest—Sections I.7.1 and I.7.2 of the source report (DOE 2002 [DIRS 155970]) provide calculations of ^{14}C release rates and the resulting individual maximum radiological dose rate. The maximum release rate is based on the amount of ^{14}C available for transport (accounting for decay and perforated cladding) as a function of time. The equations are presented clearly in Section I.7.1, and a hand-check of the calculation for the maximum release rate of 3.3 μCi per year at 1,700 years after repository closure was performed.

As presented in Section I.7.1 (DOE 2002 [DIRS 155970]), the activity (in curies) of ^{14}C available for transport, A_T, from the waste package as a function of time is calculated based on a time interval of every 100 years as follows:

$$A_T = D_F \times F_{FC} \times 0.122 \text{ Ci per package} \qquad \text{(Eq. J40-1)}$$

where:

D_F = time-dependent factor that accounts for radioactive decay (unitless)

F_{FC} = fraction of perforated cladding (unitless).

About 2% of the ^{14}C in commercial spent nuclear fuel exists as a gas in the gap space (Oversby 1987 [DIRS 103446], p. 92). Therefore, the activity of 0.122 Ci per package is determined from the specific activity of ^{14}C (4.46 Ci/g ^{14}C) (Shleien 1992 [DIRS 127299], Table 8.4.1; ^{14}C half-

life is 5,730 years with a specific activity of 0.165 TBq/g; TBq = 27.03 Ci) and the estimated mass of ^{14}C per commercial spent nuclear fuel waste package (1.37 g ^{14}C per package) (DTN: SN0310T0505503.004 [DIRS 168761]).

The time-dependent factor, D_F, is the fraction of ^{14}C remaining, given by the following equation:

$$D_F = \frac{C(t)}{C(t=0)} = e^{-\beta t} \quad \text{(Eq. J40-2)}$$

The half-life of ^{14}C is 5,730 years, so the decay constant, β, is 1.2×10^{-4} yr^{-1}. Assuming the first package fails at a time of 1,700 years after repository closure (the reported time for maximum release of 3.3 μCi per year), D_F is equal to 0.82. The fraction of perforated cladding at 1,700 years, F_{FC}, is estimated to be approximately 0.003 from the results in Figure I-28, which shows a linear increase in perforated cladding for the first 80,000 years (2% of the cladding was reported to fail in the first 10,000 years). The activity of ^{14}C available in a 100-year interval after the waste package failure at 1,700 years is then equal to $0.82 \times 0.003 \times 0.122 = 3 \times 10^{-4}$ Ci. The release rate to the surface is calculated as the available activity of ^{14}C divided by the 100-year interval, or 3 μCi/yr. This is consistent with the reported value of 3.3 μCi per year in Section I.7.1 the source report (DOE 2002 [DIRS 155970]).

Section I.7.2 presents the individual maximum radiological dose rate using a dose conversion factor of 5.6×10^{-14} rem per μCi, as calculated using the GENII code (qualified software on the YMP). For a maximum release rate of 3.3 μCi per year, the maximum dose is calculated as $5.6 \times 10^{-14} \times 3.3 = 1.8 \times 10^{-13}$ rem/yr or 1.8×10^{-10} mrem/yr, which is the value being qualified. This hand-check provides confidence that the development of these data was technically adequate and that it represents the desired property of interest (maximum dose from gaseous ^{14}C).

Section I.7.3 of the source report (DOE 2002 [DIRS 155970]) presents a screening argument for ^{222}Rn. The data to be qualified is the statement that gas-phase ^{222}Rn will decay before reaching the surface, 200 m above the repository horizon. The analysis in Section I.7.3 can also be checked by hand. The analysis calculates the time it would take for gas to reach the surface, assuming a maximum gas flow induced by repository-induced heating. The maximum gas flow, 2×10^{-7} $kg/s/m^2$ was taken from a report by Wu et al. (1995 [DIRS 103690]). The pore velocity is calculated as the maximum gas flow divided by the product of the gas density (approximately 1.2 kg/m^3 at 20ºC) and the effective rock porosity (on the order of 0.1 per SNL 2008 [DIRS 184748], Sections 6.5.3.and 6.5.7), which yields a pore velocity of $\sim 2 \times 10^{-6}$ m/s. For a distance of 200 meters between the repository horizon and the surface, the travel time is calculated as $200/2 \times 10^{-6} = 1 \times 10^{8}$ s, which is consistent with the reported 1,140 days in Section I.7.3. As a result, the estimated amount of ^{222}Rn remaining during this travel time is calculated as follows:

$$\frac{C(t)}{C(t=0)} = e^{-\beta t} \quad \text{(Eq. J40-3)}$$

where the decay constant, β, is 0.18145 $days^{-1}$. The fraction of ^{222}Rn remaining after 1,140 days is calculated to be 1×10^{-90}, as reported in Section I.7.3. Thus, the amount of ^{222}Rn remaining

by the time it reaches the surface is negligible. This hand-check and evaluation of the analysis documented in Section I.7.3 gives confidence that the development of these data was technically adequate and that it represents the desired property of interest (amount of ^{222}Rn that can reach the surface).

J40.3 DATA QUALIFIED FOR INTENDED USE

The data in DOE report (2002 [DIRS 155970], Section I.7) are appropriate for intended use. The technical assessment presented above, along with the qualifications of the personnel generating the data, provides sufficient confidence that these data can be considered qualified for intended use within FEP 2.2.11.03.0A (Gas Transport in Geosphere).

J41. FEP 2.2.12.00.0A – UNDETECTED FEATURES IN THE UZ

This FEP uses data from the following report as direct input:

Zhou, Q.; Liu, H-H.; Bodvarsson, G.S.; and Oldenburg, C.M. 2003. "Flow and Transport in Unsaturated Fractured Rock: Effects of Multiscale Heterogeneity of Hydrogeologic Properties." *Journal of Contaminant Hydrology, 60,* (1-2), 1-30. New York, New York: Elsevier. TIC: 253978. [DIRS 162133]

The data to be qualified for intended use within this FEP include:

> The results of an analysis of smaller-scale heterogeneity indicate that UZ flow and transport are governed primarily by large-scale stratigraphy, structure, and associated hydrological properties rather than by smaller-scale heterogeneity (Zhou et al. 2003 [DIRS 162133], Section 6).

The study by Zhou et al. (2003 [DIRS 162133]) implies that flow and transport in the Yucca Mountain unsaturated zone are mainly determined by large-scale heterogeneity, characterized by property differences between different geological units rather than by property variability within a geological unit.

J41.1 QUALIFICATION METHOD

The method of qualification for intended use of the data from Zhou et al. (2003 [DIRS 162133]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).
- The technical adequacy of equipment and procedures used to collect and analyze the data (#2).
- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).
- Extent and reliability of the documentation associated with the data (#9).

J41.2 TECHNICAL ASSESSMENT

Qualifications of Personnel or Organizations Generating the Data—Dr. Quanlin Zhou has B. Eng. and M. Eng. degrees in Hydrology and Water Resources from Hohai University, Nanjing, P.R. China, and a Ph.D. in Groundwater Hydrology from Technion-Israel Institute of Technology, Haifa, Israel. While at Technion, he was awarded the Miriam and Aaron Gutwirth Prize (1999) and the Irmay Prize (1998). Lawrence Berkeley National Laboratory has been responsible for simulations of UZ flow and transport since the inception of the YMP.

Data Demonstrate the Properties of Interest—The property of interest is the effect of local heterogeneity on flow. Zhou et al. (2003 [DIRS 162133]) used a two-dimensional mesh, with layer heights the same as in the UZ model, and used the same calibrated layer-scale values for the fracture and matrix hydrologic properties. Case A used uniform fracture permeability; in case B the fracture permeability was varied stochastically. The breakthrough curves for nonsorbing tracers were not significantly different in these two cases. The data is used to show that the hydrologic effect of an igneous intrusion would be insignificant because it would be limited in extent. The data from Zhou et al. (2003 [DIRS 162133]) show that a heterogeneity of fracture permeability at this scale would have a negligible effect on flow.

Confidence in the Data Acquisition or Developmental Results Is Warranted—The study by Zhou et al. (2003 [DIRS 162133]) is a sensitivity study, in which flow and transport were evaluated for a base case and for sensitivity cases with the hydrologic properties of rock layers varied on different scales. The base case used layer-uniform hydrologic properties taken from the reports by CRWMS M&O (2000 [DIRS 144426]) and Flint (1998 [DIRS 100033]). The two-dimensional grid used for this study (Zhou et al. (2003 [DIRS 162133], Figure 1) was essentially identical to that used for the site recommendation model. Thus, the site recommendation model is sufficiently similar to the current model to justify its use for sensitivity studies. The software used for the simulations was TOUGH2 V. 1.4 (Pruess et al. 1999 [DIRS 160778]) and T2R3D V.1.4 (Wu and Pruess 2000 [DIRS 153972]). This software has been qualified for the Yucca Mountain project (although for this use the software was not obtained from Software Configuration Management). Therefore both the software and input data are essentially equivalent to qualified software and data, and the use of the results of a sensitivity study to support the conclusion that heterogeneity at a scale of 10 m does not have a significant effect on tracer transport to the water table is qualified.

The software and input data are found to be essentially equivalent to qualified software and qualified data, and the results demonstrate that small scale heterogeneity would have a negligible effect on transport in the UZ.

J41.3 DATA QUALIFIED FOR INTENDED USE

The technical assessment presented above provides sufficient confidence that data from Zhou et al. (2003 [DIRS 162133]) are appropriate and are qualified for intended use in the screening justification for FEP 2.2.12.00.0A (Undetected Features in the UZ).

J42. FEP 2.3.13.03.0A – EFFECT OF REPOSITORY HEAT ON THE BIOSPHERE

This FEP uses data from the following report and textbook as direct input:

Final Report: Plant and Soil Related Processes Along a Natural Thermal Gradient at Yucca Mountain, Nevada (CRWMS M&O 1999 [DIRS 105031])

Soil Physics (Jury et al. 1991 [DIRS 102010]).

J42.1 QUALIFICATION OF DATA FROM CRWMS M&O 1999

CRWMS M&O 1999. *Final Report: Plant and Soil Related Processes Along a Natural Thermal Gradient at Yucca Mountain, Nevada.* B00000000-01717-5705-00109 REV 00. Las Vegas, Nevada: CRWMS M&O. ACC: MOL.19990513.0037. [DIRS 105031]

The following data from this report are used in FEP 2.3.13.03.0A as direct inputs:

> Shrubs removed about 31% (12% to 54%) of the total precipitation that fell during the period studied (CRWMS M&O 1999 [DIRS 105031], Executive Summary).
>
> An analysis of the percentage of shrub cover and of soil temperature at a depth of 45 cm suggests that for each 1°C increase in temperature, the shrub cover decreases by 1.2% and that of annual grasses increases by 5.5% (CRWMS M&O 1999 [DIRS 105031], Section 3.3).

J42.1.1 Qualification Method

The method of qualification of the data from the plant and soil report (CRWMS M&O 1999 [DIRS 105031]) listed above is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment included determination that the employed methodology was acceptable and determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- The technical adequacy of equipment and procedures used to collect and analyze data (#2).
- The extent to which the data demonstrate the properties of interest (#3).
- Conditions under which the data were generated may partially meet the QA program that supports the YMP license application process or postclosure science (#6).

J42.1.2 Technical Assessment

The Extent to Which the Data Demonstrate the Properties of Interest—The report presents the finding of field studies conducted during 1997 and 1998 by the YMP field biologists examining the relationship between soil temperature, soil moisture, and various aspects of the biotic community at Yucca Mountain. These studies were designed to assess the effects of potential thermal loading on biological communities. The study examined the relationship between the soil temperature and the abundance and percent cover of the species of plants. The study also evaluated the fractional removal of precipitation by shrubs. The data are used to evaluate the reduction in evapotranspiration due to repository heating for sites corresponding to the lower, mean, and upper bounds of shrub cover within FEP 2.3.13.03.0A (Effect of Repository Heat on the Biosphere). The data obtained are site-specific and appropriately demonstrate the properties of interest.

Technical Adequacy of Equipment and Procedures Used to Collect and Analyze Data—The methods used to carry out field studies are adequately described, including the location and representativeness of the study sites, sampling methods, and statistics (CRWMS M&O 1999 [DIRS 105031], Section 2). The data collection spanned a period of over one year, and therefore the values can be used to represent annual average conditions.

QA Conditions under Which the Data Were Generated—The records package for the report includes documentation of the data and data review, which was performed in accordance with quality administrative procedure, QAP-SIII-2, Rev 1. The document was prepared in accordance with the approved Technical Document Preparation Plan and was reviewed by three qualified scientists and a compliance reviewer in accordance with PRO-TS-003, Rev. 1, and with consideration of additional review criteria. The data were submitted to the Technical Data Management System database.

J42.1.3 Data Qualified for Intended Use

The data described above, obtained from the plant and soil report (CRWMS M&O 1999 [DIRS 105031]), are appropriate for intended use. The technical evaluation of the report, the associated data, and the existing documentation and records provides sufficient confidence that these data can be considered qualified for use within FEP 2.3.13.03.0A (Effect of the Repository Heat on the Biosphere).

J42.2 QUALIFICATION OF DATA FROM JURY ET AL. 1991

Jury, W.A.; Gardner, W.R.; and Gardner, W.H. 1991. *Soil Physics.* 5th Edition. New York, New York: John Wiley & Sons. TIC: 241000. [DIRS 102010]

> The datum from this report used in FEP 2.3.13.03.0A as direct input is the thermal conductivity for dry sand (Jury et al. 1991 [DIRS 102010], Table 5.5).

This parameter is used together with the data from the plant and soil report (CRWMS M&O 1999 [DIRS 105031]) to evaluate the response of plant communities to repository heat.

J42.2.1 Qualification Method

The method of qualification for intended use of the data from the textbook by Jury et al. (1991 [DIRS 102010]) is the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5). The rationale for using this method is that it was the most suitable considering the data, their existing documentation, and their intended use. The technical assessment was based on the determination that confidence in the data acquisition or development was warranted. Qualification process attributes used in the technical assessment of these data are selected from the list provided in Attachment 4 of SCI-PRO-001. Attributes specifically applicable to these data are:

- Qualification of personnel or organizations generating the data are comparable to qualification requirements of personnel generating similar data under an approved program that supports the YMP license application process or postclosure science (#1).

- The extent to which the data demonstrate the properties of interest (e.g., physical, chemical, geological, mechanical) (#3).

J42.2.2 Technical Assessment

Extent to Which the Data Demonstrate the Properties of Interest—The average value of thermal conductivity of dry sand obtained from this reference (0.42 cal cm^{-1} s^{-1} $°C^{-1}$) (Jury et al. 1991 [DIRS 102010], Table 5-5) is equal to 1.81 W/m-K. Thermal conductivity can be considered a basic property of a given material.

Qualification of Personnel or Organizations Generating the Data—The primary author of the text, Dr. William Jury, is a Distinguished Professor of Soil Physics at the University of California, Riverside, and the authority in the field of soil physics. *Soil Physics* by Jury et al. (1991 [DIRS 102010]) is the classic guide to soil physics used as a principal text in many advanced soil physics university courses.

J42.1.3 Data Qualified for Intended Use

Considering the use of the data and the results of the technical evaluation of the data and their source, there is sufficient confidence that the data obtained form the textbook by Jury et al. (1991 [DIRS 102010]) are appropriate for intended use and are qualified for the use in the screening justification for FEP 2.3.13.03.0A (Effect of the Repository Heat on the Biosphere).

J42.3 DESCRIPTION AND JUSTIFICATION OF EQUATION FROM CARSLAW AND JAEGER 1959

The approach to predicting temperature changes near the surface is to determine the flux of repository-generated heat, multiply by depth, and divide by the thermal conductivity (Carslaw and Jaegar 1959 [DIRS 100968], Equation 2):

$$\Delta T = \frac{Q \Delta z}{AK} \qquad \text{(Eq. J42-1)}$$

where Q/A is the heat flux (W/m^2), Δz is depth (m), and K is thermal conductivity of the near-surface (W/m-K).

The equation presented above is the one-dimensional representation of the law of heat conduction (Fourier's law) solved for ΔT. This equation represents fundamentals of the process of heat conduction through matter and was appropriate for intended use in FEP 2.3.13.03.0A (Effect of the Repository Heat on the Biosphere).

Data Qualification Plan

QA: QA

Page 1 of 13

Complete only applicable items.

Section I. Organizational Information

Qualification Title

Data Qualification Report: Project and External Source Data to be Qualified for Intended Use in Document ANL-WIS-MD-000027

Requesting Organization

PA/TSPA/FEPs

Section II. Process Planning Requirements

1. List of Unqualified Data to be Evaluated

Please see attached Table

2. Type of Data Qualification Method(s) [Including rationale for selection of method(s) (Attachment 3) and qualification attributes (Attachment 4)]

Methods, rationales and attributes associated with each data are listed in the attached Table.

3. Data Qualification Team and Additional Support Staff Required

Qualification Chairperson—Susan Boggs
Data Qualification Team Members—Alicia Aragon; Maryla Wasiolek; Robert Jones
The data qualification team members are independent from the data collected or data reduction process.

4. Data Evaluation Criteria

Data evaluation criteria are based on consideration of the attributes identified above and arriving at an affirmative conclusion that a given attribute is met by the data under consideration.

5. Identification of Procedures Used

SCI-PRO-005, Section 6.2.1.M.3

6. Plan coordinated with the following known organizations providing input to or using the results of the data qualification

Performance Assessment sub-organization/disciplines, as applicable.
All PA sub-organizations/disciplines

Section III. Approval

Qualification Chairperson Printed Name	Qualification Chairperson Signature	Date
Susan Boggs		2/28/08
Responsible Manager Printed Name	**Responsible Manager Signature**	**Date**
M. Kathryn Knowles		2/28/08

SCI-PRO-001.1-R1

Input	Source	Description	FEP	Project or External	Method[1] (Rationale)[2]	Attribute[3]
CRWMS M&O 1999. *Final Report: Plant and Soil Related Processes Along a Natural Thermal Gradient at Yucca Mountain, Nevada*. [DIRS 105031]	Executive Summary	Shrubs removed about 31% (12% to 54%) of the total precipitation that fell during the period studied	2.3.13.03.0A	P	5 (b)	2, 3, 6
	Section 3.3	An analysis of the percentage of shrub cover and of soil temperature at a depth of 45 cm suggests that for each 1°C increase in temperature, the shrub cover decreases by 1.2% and that of annual grasses increases by 5.5%	2.3.13.03.0A	P	5 (b)	2, 3, 6
DOE 2002. *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada*. [DIRS 155970]	Section I.7	Modeling of potential annual doses from gas-phase geosphere transport of ^{14}C shows that the individual maximum radiological dose is 1.8×10^{-10} mrem/yr, which corresponds to a maximum gas-phase release rate that occurs at 1,700 years following repository closure	2.2.11.03.0A	P	5 (c)	1, 2, 3
	Section I.7.3	Based on gas flow studies, radon released from the repository in the gas phase is expected to radioactively decay before reaching the ground surface	2.2.11.03.0A	P	5 (c)	1, 2, 3
Doorenbos and Pruitt 1977. *Crop Water Requirements*. [DIRS 103062]	Table 36, p. 78	The data from this reference that are being used as direct input are the salinity tolerances for crop	2.2.08.07.0C	E	5 (d)	1, 3
Ehlers and Blatt 1982. *Petrology, Igneous, Sedimentary, and Metamorphic*. [DIRS 167802]	pp. 684 to 685	The geothermal gradient at convergent plate boundaries may range from less than 10°C per km to greater than 25°C per km	1.2.05.00.0A	E	2 (e)	3, 10
	p. 566	Conditions conducive to the onset of regional metamorphism correspond to temperature of 150°C to 200°C and pressures of 0.5 to 1 kilobars, which occur at depths of 4 to 5 km	1.2.05.00.0A	E	2 (e)	3, 10

Table J-2. Data Qualification Plan for Project Data, Project and External Source Data to Be Qualified for Intended Use in Document ANL-WIS-MD-000027 (Continued)

Input	Source	Description	FEP	Project or External	Method[1] (Rationale)[2]	Attribute[3]
Finch and Ewing 1992. "The Corrosion of Uraninite Under Oxidizing Conditions." [DIRS 113030]	Section 4.2.2	The effect of dissolved silica on the alteration of the UOHs (uranyl oxide hydrates) is profound; the alteration of schoepite can result in the formation of uranyl silicates such as uranophane and soddyite	2.1.09.15.0A	E	2 (e)	3, 8, 10
Freeze and Cherry 1979. *Groundwater*. [DIRS 101173]	pp. 514 to 515	Extensive carbonate dissolution cavities are not expected to develop because such dissolution is not typically observed in carbonates at great depths below the water table	1.2.09.02.0A	E	5 (b)	1, 3
	p. 106	Carbonate, quartz, and halite solubilities	1.2.09.02.0A	E	5 (b)	1, 3
Fridrich et al. 1998. *Space-Time Patterns of Late Cenozoic Extension, Vertical-Axis Rotation, and Volcanism in the Crater Flat Basin, Southwest Nevada*. [DIRS 164051]	pp. 1	During the period of peak tectonism (approximately 11.6 Ma to 12.7 Ma), the western part of Crater Flat basin subsided due to the basin extending from 18% to 40% in 1.1 million years or less	1.2.01.01.0A	P	5 (b)	2, 3, 8
	pp. 1, 13, 19 and 20	After 11.6 Ma, the rate of extension in the basin declined in a roughly exponential manner. The late Quaternary rate of extension is less than 1% of the initial rate (Fridrich et al. 1998 [DIRS 164051], pp. 1 and 13) and may be as low as 0.1% to 0.2% per million years (Fridrich et al. 1998 [DIRS 164051], pp. 19 and 20).	1.2.01.01.0A	P	5 (b)	2, 3, 8
	pp. 1 and 2	The pattern of Quaternary deformation mimics the pattern of middle Miocene activity, but at substantially lower rates (Fridrich et al. 1998 [DIRS 164051], pp. 1 and 2).	1.2.01.01.0A	P	5 (b)	2, 3, 8

Smyth and Caporuscio 1981. *Review of the Thermal Stability and Cation Exchange Properties of the Zeolite Minerals Clinoptilolite, Mordenite, and Analcime: Applications to Radioactive Waste Isolation in Silicic Tuff*. [DIRS 174060]	Tables A-1 and B-1, sample YM-40	Volume and weight changes observed upon heating were recorded for a rock sample from the zeolitized Calico Hills Formation. The tuff was soaked in water at 91°C for 48 hours and then kept at approximately 95°C in a drying oven. The core was weighed and measured at the beginning of the experiment and periodically throughout the 32-hour dry-heating period. The amount of water lost between the highest measured volume (hour 1) and the next measurement (hour 2), relative to the total water lost during heating, was 70.6 wt % calculated as 100 × (19.77033 g – 18.5134 g)/ (19.7703 g – 17.9906 g)	2.2.10.14.0A	P	5 (b)	1, 3
	Table A-1, sample YM-38	The selected upper bounding value for volume reduction of initially saturated zeolitic tuff heated in air at 95°C was 0.76 vol %	2.2.10.14.0A	P	5 (b)	1, 3
Stuckless and Levich 2007. *The Geology and Climatology of Yucca Mountain and Vicinity, Southern Nevada and California*. [DIRS 181507]	p. 83	Using a ^{10}Be cosmogenic dating technique, the calculated maximum possible erosion rates for bedrock outcrops at Yucca Mountain range from 0.4 to 2.7 cm/10,000 years	1.2.07.01.0A	P	2, 5 (a) and (b)	3, 7, 9
	p. 84	The long-term rates of erosion of unconsolidated material from Yucca Mountain hillslopes were calculated to be 0.2 to 6 cm/10,000 years using the rock varnish cation ratio and the in situ cosmogenic ^{36}Cl dating methods	1.2.07.01.0A	P	2, 5 (a) and (b)	3, 7, 9

[DIRS 174060]	Tables A-1 and B-1 (sample YM-40)	Dehydration and shrinkage of zeolitic tuff under experimental heating conditions
	Table A-1, sample YM-38	Upper bounding value for volume reduction of initially saturated zeolitic tuff under experimental heating conditions
Stuckless and Levich 2007. *The Geology and Climatology of Yucca Mountain and Vicinity, Southern Nevada and California*. [DIRS 181507]	p. 83	The calculated maximum possible erosion rates for bedrock outcrops using a ^{10}Be cosmogenic dating technique is 0.4 to 2.7 cm/10,000 years
	p. 84	The long-term erosion rates of stripping of unconsolidated material from Yucca Mountain hillslopes were calculated to be 0.2 to 6 cm/10,000 years using both the rock-varnish carion ratio and the in situ, ^{36}Cl cosmogenic dating methods
Taylor 1986. *Impact of Time and Climate on Quaternary Soils in the Yucca Mountain Area of the Nevada Test Site*. [DIRS 102864]	Chapter 5	SiO_2 cementation is not dependent on climatic conditions, but cementation does exhibit distinctive trends that correspond with the ages of the surficial deposits
	Figure 9 and pp. 31 to 33	Cementation by opaline SiO_2 is common in the study area, and that opaline SiO_2 accumulation in the soils is favored over that of pedogenic calcite $CaCO_3$

Table J-3. Direct Inputs for Appendix J (Continued)

Input	Source	Description
Taylor 1986. *Impact of Time and Climate on Quaternary Soils in the Yucca Mountain Area of the Nevada Test Site*. [DIRS 102864] (continued)	Chapter 5	Accumulation rates are attributable to several climatic scenarios, but climate change was insufficient to significantly decrease the rate of accumulations
Thompson et al. 1999. *Quantitative Paleoclimatic Reconstructions from Late Pleistocene Plant Macrofossils of the Yucca Mountain Region*. [DIRS 109470]	Figures 17, 18	During the last glacial maximum, the mean annual temperature at Yucca Mountain exceeded 0°C
Valentine and Krogh 2006. "Emplacement of Shallow Dikes and Sills Beneath a Small Basaltic Volcanic Center – The Role of Pre-Existing Structure (Paiute Ridge, Southern Nevada, USA)." [DIRS 177282]	p. 221	The resulting effects of dike intrusion may be to increase, decrease or not change permeabilities as compared to the host (unaffected) rock. The scale at which permeabilities would change is limited to a few meters around the dike
Valentine et al. 1998. "Physical Processes of Magmatism and Effects on the Potential Repository: Synthesis of Technical Work Through Fiscal Year 1995." [DIRS 119132]	p. 5-74	Mineral alterations around igneous intrusions at natural analogue sites show that alteration is limited to a zone that extends less than 10 m away from the intrusion/host rock contact around igneous intrusions at natural analogue sites
Wachs, G. 2004. *Calculation of Amount of Free Water Required to Overpressurize DOE SNF Standardized Canister and RW Waste Package*. [DIRS 184624]	Section 6	The volume of free (unbound) water is approximately 0.0005 liters in a 15-foot-long DOE SNF Standardized Canister after cold vacuum drying
Whelan 2004. *Secondary Mineral Deposits and Evidence of Past Seismicity and Heating of the Proposed Repository Horizon at Yucca Mountain, Nevada*. [DIRS 170697]	p. 3	Description of the process of infilling and coating of open fractures and lithophysal cavities by calcite and silica at Yucca Mountin.
Wilson et al. 2003. "Origin, Timing, and Temperature of Secondary Calcite—Silica Mineral Formation at Yucca Mountain, Nevada." [DIRS 163589]	Section 8	Studies of secondary minerals at Yucca Mountain using petrography, fluid inclusion thermometry, and uranium-lead dating indicate that unsaturated-zone temperatures have remained close to the current ambient values over the past 2 to 5 Ma
	Sections 7.3, 8	The unsaturated-zone secondary minerals were interpreted to have been deposited from downward percolating meteoric water and not the result of upwelling groundwaters
Wronkiewicz et al. 1996. "Ten-Year Results from Unsaturated Drip Tests with UO_2 at 90°C: Implications for the Corrosion of Spent Nuclear Fuel." [DIRS 102047]	p. 86	Between 1% and 12% of the total amount of uranium released was present as a >5 nm size-fraction
Zhang and Schwartz 1995. "Multispecies contaminant plumes in variable density flow systems." [DIRS 183479]	pp. 839, 840, 843, and 844	The chemical and physical properties of the leachate for a specified discharge and the medium
Zhou et al. 2003. "Flow and Transport in Unsaturated Fractured Rock: Effects of Multiscale Heterogeneity of Hydrogeologic Properties." [DIRS 162133]	Section 6	An analysis of smaller-scale heterogeneity indicates that UZ flow and transport are governed primarily by large-scale stratigraphy, structure, and associated hydrological properties rather than by smaller-scale heterogeneity

10. Revision and Addendum No.	11. Description of Change
REV 00, ADDENDUM 01	The screening justifications for FEPs 1.2.03.02.0B, *Seismic Induced Rockfall Damages EBS Components*; 1.2.03.02.0E, *Seismic-Induced Drift Collapse Alters In-Drift Chemistry;* 1.2.10.01.0A, *Hydrologic Response to Seismic Activity*; 2.2.06.01.0A, *Seismic Activity Changes Porosity and Permeability of Rock*; 2.2.06.02.0A, *Seismic Activity Changes Porosity and Permeability of Faults*; 2.2.06.02.0B, *Seismic Activity Changes Porosity and Permeability of Fractures*; and 2.2.06.03.0A, *Seismic Activity Alters Perched Water Zones* are updated to reflect additional analyses. Appendix K[a] is added to the report to document bounding water table rise calculations consistent with the probabilistic seismic hazard analysis for Yucca Mountain. These changes address Condition Reports 13736 and 13839. Also, the screening justification for FEP 2.1.03.04.0B, *Hydride Cracking of Drip Shields*, is modified to add consideration of the initial hydrogen content of the titanium alloys discussed and to refer to "calculated hydrogen content" as "calculated hydrogen pick-up." These changes address Condition Report 13386. For FEPs 2.1.09.02.0A, *Chemical Interaction with Corrosion Products* and 2.1.09.17.0A, *Formation of Pseudo-Colloids (Corrosion Product) in EBS*, the total system performance assessment disposition is changed to clarify the sorption of plutonium and americium onto oxyhydroxide colloids is a kinetic process in the engineered barrier system. The changes result from resolution of Condition Report 13644. In addition, impacts to tables for FEPs 2.1.14.26.0A (Near-Field Criticality Resulting from an Igneous Event), and 2.2.14.12.0A (Far-Field Criticality Resulting from an Igneous Event), resulting from an update to SNL 2007 [DIRS 181395] are implemented. The changes result from resolution of Condition Reports 14019 and 14087. Finally, screening justifications for FEPs 1.2.07.01.0A, *Erosion/Denudation*, and 2.3.01.00.0A, *Topography and Morphology*, are modified to update the citation to *Reclamation Implementation Plan* (YMP/91-14) (DOE 2009 [DIRS 185964]). This addresses an issue associated with Condition Report 13388.

INTENTIONALLY LEFT BLANK

1[a]. PURPOSE

This addendum supplements the discussion of seismically related features, events, and processes (FEPs) in *Features, Events, and Processes for the Total System Performance Assessment: Analyses* (ANL-WIS-MD-000027 REV00) ("the parent report"). The supplemental discussion establishes the consistency between exclusion screening justifications and levels of ground motion used in postclosure analyses. It also examines the consistency of seismic source characterization data and fault displacement hazard results from the probabilistic seismic hazard analysis (PSHA) for Yucca Mountain with bounding estimates of earthquake-related water table rise used in the exclusion screening justification for FEP 1.2.10.01.0A, *Hydrologic Response to Seismic Activity*. These supplemental discussions address the issue identified in Condition Report 13736.

In addition, this addendum supplements the screening justification for FEP 1.2.10.01.0A, *Hydrologic Response to Seismic Activity*, to discuss relevant literature on earthquake-related hydrologic effects that was not previously cited. This supplemental discussion, in combination with the supplemental discussions mentioned in the previous paragraph, address the issue identified in Condition Report 13839.

Supplemental discussions are provided for seismically related FEPs that are excluded from the total system performance assessment (TSPA):

- 1.2.03.02.0B, *Seismic Induced Rockfall Damages EBS Components*
- 1.2.03.02.0E, *Seismic-Induced Drift Collapse Alters In-Drift Chemistry*
- 1.2.10.01.0A, *Hydrologic Response to Seismic Activity*
- 2.2.06.01.0A, *Seismic Activity Changes Porosity and Permeability of Rock*
- 2.2.06.02.0A, *Seismic Activity Changes Porosity and Permeability of Faults*
- 2.2.06.02.0B, *Seismic Activity Changes Porosity and Permeability of Fractures*
- 2.2.06.03.0A, *Seismic Activity Alters Perched Water Zones*

Also, the screening justification for FEP 2.1.03.04.0B, *Hydride Cracking of Drip Shields*, is modified to add consideration of the initial hydrogen content of the titanium alloys discussed and to refer to "calculated hydrogen content" as "calculated hydrogen pick-up." This change is an impact resulting from resolution of the issue identified in Condition Report 13386. Justification of the change and analysis of impacted documents is found in SNL (2007 [DIRS 181339]).

For FEP 2.1.09.02.0A, *Chemical Interaction with Corrosion Products* and FEP 2.1.09.17.0A, *Formation of Pseudo-Colloids (Corrosion Product) in EBS*, the TSPA disposition is changed to clarify the sorption of plutonium and americium onto oxyhydroxide colloids is a kinetic process in the engineered barrier system (EBS). This change is an impact resulting from resolution of the issue identified in Condition Report 13644. Justification of the change and analysis of impacted documents is found in *EBS Radionuclide Transport Abstraction* (SNL 2007 [DIRS 177407]).

In addition, the screening justifications for FEP 2.1.14.26.0A, *Near-Field Criticality Resulting from an Igneous Event* and FEP 2.2.14.12.0A, *Far-Field Criticality Resulting from an Igneous Event*, are modified to update Table 2.1.14.26.0A-1 and Table 2.2.14.12.0A-1, respectively.

These changes represent an impact resulting from the resolution of the issues identified in Condition Reports 14019 and 14087. Errors were corrected in two cases in which the external accumulation model was executed. Justification of the change and analysis of impacted documents is found in SNL (2007 [DIRS 181395].

Finally, screening justifications for FEPs 1.2.07.01.0A, *Erosion/Denudation* and 2.3.01.00.0A, *Topography and Morphology*, are modified to update the citation to the *Reclamation Implementation Plan* (YMP/91-14) (DOE 2009 [DIRS 185964]). This addresses an issue associated with Condition Report 13388.

The supplemental discussions and modifications do not alter any screening decisions.

The following Condition Reports are currently open and affect the parent report, but will not be addressed in this addendum because work to resolve the related issues has not yet been completed:

- Condition Report 14133, *Incomplete descriptions of radioactive volatile components during volcanic eruption in FEP evaluations*
- Condition Report 14112, *Inconsistencies in use of control parameters in ANL-WIS-MD-000024, ANl-WIS-MD-000027, and TDR-BGR-MD-000037*
- Condition Report 14016, *Water-rock interactions not considered in the assumption of secular equilibrium for the transport of Ac-227, Ra-228, and Pb-210*

2[a]. QUALITY ASSURANCE

Development of this addendum and the supporting activities are subject to the Office of Civilian Radioactive Waste Management Quality Assurance Program *Quality Assurance Requirements and Description* (DOE 2009 [DIRS 185965]).

Preparation of this addendum is controlled by SCI-PRO-005, *Scientific Analyses and Calculations*, and other Lead Lab procedures referenced therein. Electronic management of information is controlled as described in *Technical Work Plan for the Performance Assessment Features, Events, and Processes* (TWP-WIS-MD-000036 REV03) (SNL 2007 [DIRS 184327]) and in accordance with IM-PRO-002, *Control of the Electronic Management of Information*.

INTENTIONALLY LEFT BLANK

3[a]. USE OF SOFTWARE

No qualified software was used in carrying out analyses documented in Addendum 01. Controlled unqualified software, which is exempt from software qualification in accordance with IM-PRO-003 Section 2, was used for data organization and simple calculations as documented in Appendix K[a], which includes the electronic file, *PSHA Static Stress Drops R1.xls*. All calculations were carried out using Microsoft® Excel® 2003.

Seismic-Induced Rockfall Damages EBS Components

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*The following unnumbered section is added to the discussion.*]

Vibratory Ground Motion–Rockfall in the nonlithophysal lithostratigraphic units is evaluated for ground motion with a horizontal (H1) peak ground velocity (PGV) of about 40, 105, 244, and 535 cm/sec (BSC 2004 [DIRS 166107], Table 6-5). This set of PGV values is based on results of the probabilistic seismic hazard analysis (PSHA) for Yucca Mountain and ground motion site-response modeling (BSC 2004 [DIRS 170027], Table E-1). The set corresponds to ground motion hazard with mean annual probabilities of exceedance of 10^{-4}, 10^{-5}, 10^{-6}, and 10^{-7}, respectively, based on the PSHA results.

For PGV values of 105, 244, and 535 cm/sec, 17 three-component sets of time histories are developed for use in rockfall analyses (BSC 2004 [DIRS 170027], Section 6.3.2.3). Recorded strong motion records with appropriate magnitude and distance characteristics form the basis for the developed time histories. The H1 component of each set is scaled to the target PGV level (i.e., 105, 244, or 535 cm/sec) and the other components (H2, V) are scaled to maintain the inter-component variability of the original seismograms.

For a PGV value of 40 cm/sec, one set of three-component time histories was developed. As this set was primarily for preclosure analyses, a different scaling approach was implemented. A recorded strong motion record with appropriate magnitude and distance characteristics was

adjusted such that its response spectra matched the target design response spectra with a mean annual probability of exceedance of 10^{-4}.

Subsequent to the development of time histories, new findings indicated that, at low probabilities, the PSHA hazard curves are inconsistent with the geologic setting at Yucca Mountain (BSC 2005 [DIRS 170137], Section 6; SNL 2009 [DIRS 185977], Section 6.1). That is, the mean annual probability of exceedance for a given level of ground motion is too high. When the hazard curves are conditioned to take the new findings into account, a horizontal (H1) PGV of 4.07 m/sec is found to have a mean annual probability of exceedance of 10^{-8} (BSC 2005 [DIRS 170137], Section 6.8; SNL 2007 [DIRS 176828], Section 6.4.3). The mean annual probabilities of exceedance for the PGV levels associated with the time history suites used in the nonlithophysal rockfall modeling become 10^{-4}, 10^{-5}, 4.5×10^{-7}, and significantly lower than 10^{-9}. Thus, rockfall results for a horizontal PGV of 535 cm/sec are so unlikely that they need not be considered in the screening evaluation for the performance assessment. This result is taken into account in assessing the consequences of seismically induced rockfall in nonlithophysal rock units.

FEP NAME:

Seismic-Induced Drift Collapse Alters In-Drift Chemistry

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*The second paragraph is modified as follows:*]

Although limited rockfall may occur in nonlithophysal host rock units, drift collapse is expected to occur in the lithophysal host rock units, which are characterized by lithophysal voids interconnected by intense fracturing as discussed in *Drift Degradation Analysis* (BSC 2004 [DIRS 166107], Section 6.4.1.1). Postclosure ground motion in lithophysal rock could result in substantial or complete drift collapse (SNL 2007 [DIRS 176828], Section 6.7.1). This justification assumes that seismically induced drift collapse has occurred and thus is not dependent on the level of ground motion that collapses the drift or its mean annual probability of exceedance. The seismically induced drift collapse affects the hydrologic and thermal environment in the EBS. Seepage could increase because the greater span and irregular shape of collapsed drift openings will reduce the effectiveness of the drift wall due to the capillary barrier effect (SNL 2007 [DIRS 181244], Section 6.3). The temperature of the drip shields and waste packages will increase relative to uncollapsed drifts because the drift rubble acts as an insulating blanket over the drip shield (SNL 2008 [DIRS 184433], Section 6.3.17[a]).

FEP NAME:

Hydrologic Response to Seismic Activity

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*The Screening Justification is replaced by the following paragraphs:*]

The potential effects of seismic activity on the geology and hydrology of Yucca Mountain are considered under a series of FEPs. This FEP addresses potential effects of seismic activity on the elevation of the water table, on the large hydraulic gradient that exists to the north of the repository, and on ground water chemistry. Potential effects of seismic activity on flow and transport caused by changes in the properties of the rock matrix, faults, and fractures are considered separately under FEPs 2.2.06.01.0A, *Seismic Activity Changes Porosity and Permeability of Rock*, 2.2.06.02.0A, *Seismic Activity Changes Porosity and Permeability of Faults*, and 2.2.06.02.0B, *Seismic Activity Changes Porosity and Permeability of Fractures*, respectively. Potential effects of earthquake-induced drift collapse on flow and transport through emplacement drifts are assessed under FEP 1.2.03.02.0D, *Seismic-Induced Drift Collapse Alters In-Drift Thermohydrology*.

Seismic Effects on Water Table Elevation

Seismic effects on water table elevation fall into two categories (e.g., Montgomery and Manga 2003 [DIRS 186262]): transient and sustained. The transient response is due to the passage of seismic waves and has a duration of minutes. Sustained responses can arise from volumetric strain in the rock, changes in permeability, or compaction of unconsolidated deposits. These responses typically have durations of months and dissipate primarily by the lateral flow of groundwater from areas with a higher water table elevation to the surrounding areas with a lower water table elevation. Both of these responses are short-lived in comparison to the 10,000- and 1,000,000-year compliance periods relevant to the performance assessment of the Yucca Mountain repository.

The significance of a rise in the water table is that it reduces the contribution to the barrier capability of the unsaturated zone by shortening the flow path from the repository to the saturated zone. Conceptually, an earthquake-induced water table rise could eliminate the gap between the water table and emplacement drifts and thereby alter the in-drift environment.

Within the repository footprint, the present-day water table varies from around 730 m above mean sea level in the south to less than 850 m above mean sea level in the north (BSC 2004 [DIRS 169855], Figure 6-2). The repository elevation for emplacement drifts ranges between 1,037 m above mean sea level in the north (BSC 2007 [DIRS 179640], Table 14) and 1,105 m above mean sea level in the south (BSC 2007 [DIRS 179640], Table 12), indicating that the present-day water table depth below the repository horizon ranges from 187 m in the north, based on a repository elevation of 1,037 m and water table elevation of 850 m, to 375 m in the south, based on a repository elevation of 1,105 m and water table elevation of 730 m. For future, wetter climates, the elevation of the water table is taken to have a uniform value of 850 m. Thus, if earthquake-induced water table rise is less the minimum 187 m distance between the elevation of the water table and the lowest elevation of a waste emplacement drift, this effect can be excluded from the TSPA.

Szymanski (1989 [DIRS 106963]) proposed that earthquake-related changes in stress could affect fracture apertures, restricting the ability of water to drain from the Yucca Mountain site and causing a change in the heat-flow regime. He hypothesized that the combined effect of these changes would lead to a rise in the elevation of the water table. Veins of calcium carbonate and silica observed in local faults were interpreted as evidence of past elevated water tables supporting the hypothesis.

To obtain an independent assessment of the hypothesis, DOE asked the National Academy of Sciences' National Research Council to evaluate if the water table at Yucca Mountain had been raised in the geologically recent past to the level of the proposed repository and if such a water table rise was likely to occur within the next 10,000 years. To this end, the National Research Council established the Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain, Nevada ("the Panel").

The Panel considered two models of earthquake-related water table rise: a dislocation model and a regional stress change model (National Research Council 1992 [DIRS 105162], Chapter 5). Analyses using the dislocation model approach were carried out by Carrigan et al. (1991 [DIRS 100967]) and Bredehoeft (1992 [DIRS 101122]). For typical Basin and Range earthquakes (normal faulting with 1-m slip), Carrigan et al. (1991 [DIRS 100967]) used a two-dimensional model and found the increase in water table elevation was 2 to 3 m for different combinations of elastic properties and aquifer thickness. Extrapolating their results to larger slip values, they found that for a 4-m slip earthquake a water table rise of 17 m was predicted. For a fault-patch model that produced greater strains and stresses, water table rise ranged from 6 to 12 m for different permeability assumptions. Bredehoeft (1992 [DIRS 101122]) used a three-dimensional model to analyze a normal faulting earthquake with 1 m slip whose rupture was 30-km long and extended at a 60-degree dip to a depth of 10 km. For this case, Bredehoeft found that the head change produced by the earthquake was quickly dissipated by local flow. The impact on the water table elevation was a rise on the order of 1 m.

The Panel focused its attention on the regional stress change model because it resulted in a larger earthquake-induced water table rise. The Panel expanded on work by Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]) who developed a simple representation of the poroelastic response of the earth's crust to a regional change in stress caused by a normal-faulting earthquake and the consequent effect on the elevation of the water table. In the Kemeny and

Cook representation, the earthquake causes a regional increase in volumetric strain that reduces the pore volume, increasing pore pressure, and resulting in water moving upward to fill pore space above the elevation of the preexisting water table. To create a simple representation that bounds the amount of water table rise, conservative assumptions are made. These assumptions include (Kemeny and Cook 1990 [DIRS 129658], Section 5.3.2):

- All water displaced from the volume due to coseismic stress change goes up the stratigraphic column instantaneously.

- The coseismic volumetric stress change following a normal-faulting earthquake is compressional, uniform with depth, and extends over the vertical extent of faulting.

The first assumption results in immediately propagating the fluid volume displaced from the rock by compression to the water table. It thus gives an upper bound on the water level change. Factors that will reduce the amplitude of the change include time-dependent flow, flow directions other than upward, and impermeable beds. While water level changes can occur rapidly in open boreholes intersecting areas of compressed or dilated rock following poroelastic deformation due to an earthquake, the propagation of these changes to the water table is much less pronounced. Essentially, the excess pore pressure would be dissipated in the more permeable rock units and is not propagated vertically through aquitards and low permeability stratigraphic units to the water table surface.

The second assumption results in displacement of water throughout the volume of rock in the vicinity of the fault. This is conservative because evidence now shows that observed deformations associated with earthquake fault displacements are not uniformly compressive, but rather include areas that undergo dilation (thus potentially lowering the observed water level for any wells intersecting these zones) and others that undergo compression (thus potentially raising the observed water level for any wells intersecting these zones). That is, coseismic poroelastic strains are not uniformly compressive and do not appear to be constant with depth, but instead have a three-dimensional pattern consistent with a dislocation model of fault displacement.

Using the regional stress change approach and conservative assumptions, Kemeny and Cook obtain a simple mechanical model relating water table rise to the static stress drop associated with an earthquake and the vertical extent of faulting:

$$\Delta w = (1.2 \times 10^{-5}) \times \Delta\sigma_{static} \times h$$

in which Δw is water table rise in meters, $\Delta\sigma_{static}$ is static stress drop in bars, and h is depth of faulting in meters. For a static stress drop of 100 bars and a 10 km vertical extent of faulting, the Kemeny and Cook model gives a bounding water table rise of about 10 m (National Research Council 1992 [DIRS 105162], p. 114). The National Research Council used a similar model and looked at the sensitivity to alternate rock and hydrologic properties. Based on their results and the other information available to them (e.g., results from the dislocation models), the Panel concluded that "only a modest rise in the water table of less than 50 m is likely to occur as the result of a nearby earthquake."

The Panel considered a static stress drop of 100 bars as a reasonable upper value to assess the potential for water table rise during a 10,000-year performance period. Other seismic work for Yucca Mountain implies that larger static stress drops are possible for earthquakes near the site. Seismic source characterization and fault displacement hazard results from the probabilistic seismic hazard analysis (PSHA) for Yucca Mountain can be interpreted in terms of static stress drop. In addition, the stress parameter associated with the point-source stochastic ground motion model that is used in one approach to characterize extreme ground motions at Yucca Mountain can be related to static stress drop in a general sense.

Implications of PSHA Results. Seismic source characterization carried out by six expert teams as part of the PSHA for Yucca Mountain (DTN: MO0401MWDRPSHA.000 [DIRS 185267]) contains information on the geometry and maximum magnitudes of fault sources contributing to the ground motion hazard at the site. This information can be used to infer a static stress drop for the maximum magnitude earthquake and the consequent bounding water table rise determined using the Kemeny and Cook model (Appendix K[a]). For 3139 out of the 3150 fault characterization cases developed as part of the PSHA, the calculated water table rise is less than the 187 m distance between the elevation of the water table and the lowest waste emplacement drift. This observation is independent of the probability that a given case represents the actual geologic conditions at Yucca Mountain. When seismic source characterization probabilities are taken into account along with the rate of occurrence of M_{max} events, it is determined that 7 of the 11 cases for which calculated water table rise exceeds 187 m have probabilities more than an order of magnitude less than 10^{-8}. Thus, for the Kemeny and Cook model only four cases resulting in a calculated water table rise exceeding 187 m have probabilities greater than 10^{-8}. Taking into account the intentional bounding nature of the Kemeny and Cook model (e.g., conservative assumptions that poroelastic deformation is everywhere compressional and that all displaced water instantaneously moves vertically), the results support exclusion of seismically induced water table rise from the TSPA.

Fault displacement hazard results from the PSHA (DTN: MO0401MWDRPSHA.000 [DIRS 185267]) also demonstrate that seismically induced water table rise can be excluded from the TSPA (Appendix K[a]). For the fault sites and conditions evaluated in the PSHA, the Solitario Canyon fault has the greatest displacement hazard. For a mean annual probability of exceedance of 10^{-8}, the fault displacement hazard is about 1300 cm. Using this value as the average displacement on the Solitario Canyon and Paintbrush Canyon faults, static stress drop can be calculated using the fault geometry data from the PSHA seismic source characterization. Cases for the Solitario Canyon and Paintbrush Canyon faults alone, and in combination with other faults, give a maximum bounding water table rise of 122 m. Thus, calculated earthquake-induced water table rise using this approach maintains a gap of 65 m or more between the elevation of the water table and the lowest waste emplacement drift.

Implications of Extreme Ground Motion Conditioning. The point-source ground motion model is used to characterize extreme ground at Yucca Mountain, given a probability distribution for extreme stress parameter (point-source stress drop) (SNL 2009 [DIRS 185977], Section 6, Appendix A). To examine the implications of this analysis for potential earthquake-induced water table rise, the relation between stress parameter and static stress drop is required.

Static stress drop for a circular rupture is given by (Kanamori and Anderson 1975 [DIRS 182963]):

$$\Delta\sigma_{static} = \frac{7}{16}\frac{M_0}{a^3} \quad \text{(Eq. 1[a])}$$

in which M_0 is the earthquake moment and a the radius of the circular rupture. For a rectangular rupture expressed in terms of length (L) and width (W), an equivalent radius can be expressed as:

$$a^2 = \frac{L \times W}{\pi} \quad \text{(Eq. 2[a])}$$

The linkage between the static stress drop and the stress parameter is through the effects of source finiteness. The omega-squared (frequency-squared) source model is a widely accepted way to describe the frequency dependence of earthquake ground motion (Aki and Richards 1980 [DIRS 150723], Section 14.1). For a rectangular rupture, the frequency-squared dependence of the far field source model is due to the combination of a finite rupture length and associated duration of rupture, as well as a finite time for the slip to attain its maximum value along the rupture (rise time). For the circular rupture model of Brune, the frequency-squared dependence is due to the rupture finiteness alone; slip being theoretically instantaneous at all points on the rupture surface (Brune 1970 [DIRS 103315], 1971 [DIRS 131516]). Since the rise time is much shorter than the rupture duration (Heaton 1990 [DIRS 186296]), it is neglected in this model and the characteristic source duration (τ) is simply the time required to propagate from the center of the circular rupture to the edge:

$$\tau = \frac{a}{V_R} \quad \text{(Eq. 3[a])}$$

in which V_R is the rupture velocity and a the source radius, which can be replaced by L for length in a rectangular rupture. The characteristic duration gives rise to the corner frequency (f_C) in the omega-squared model:

$$f_C \propto \frac{1}{\tau} \propto \frac{V_R}{L} \quad \text{(Eq. 4[a])}$$

The static stress drop for a general source is given by:

$$\Delta\sigma_{static} = C\,\mu\,\frac{\bar{u}}{L} \quad \text{(Eq. 5[a])}$$

in which C is a geometric constant (7/16 for a circular rupture), μ is the shear modulus, and $\left(\frac{\bar{u}}{L}\right)$ is the strain drop (average slip ($\bar{u}$) over the characteristic dimension of the rupture (L)). Substituting the definition of moment:

$$M_0 = \mu\,\bar{u}L^2 \quad \text{(Eq. 6[a])}$$

in which (L^2) is a characteristic rupture area, into Equation 5[a] results in:

$$\Delta\sigma_{static} = C\,\frac{M_0}{L^3} \quad \text{(Eq. 7[a])}$$

and from Equation 4[a]:

$$\Delta\sigma_{static} = C\ M_0\ \left(\frac{f_C}{V_R}\right)^3 \quad \text{(Eq. 8[a])}$$

Static stress drop, therefore, shows the same functional dependence on M_0 and f_C as does stress parameter ($\Delta\sigma_{SP}$) (Silva et al. 1996 [DIRS 110474], Section 2.2):

$$\Delta\sigma_{SP} = 8.44\ M_0\ \left(\frac{f_C}{\beta}\right)^3 \quad \text{(Eq. 9[a])}$$

Although theoretically linked, static stress drop and stress parameter show a lack of correlation on an individual earthquake basis. Also, they differ in their relation to strong ground motion. Strong ground motion is correlated to stress parameter, which is related to the dynamics of fault rupture. Static stress drop shows a poor correlation to strong ground motion. For this FEP evaluation, the value of static stress drop is taken as equal to the value of stress parameter.

In the point-source modeling to characterize extreme ground motion at Yucca Mountain, a probability distribution was defined for an extreme stress parameter. The extreme stress parameter is the largest stress parameter consistent with the geologic and tectonic setting of Yucca Mountain. In considering the extreme-stress-drop distribution in this screening evaluation, first its probability of exceedance must be addressed. The likelihood of an extreme-stress-drop earthquake can be evaluated in terms of two components: (1) the earthquake recurrence frequency for local faults at Yucca Mountain and (2) the observed distribution of earthquake stress parameters.

As part of the PSHA for Yucca Mountain, a recurrence relation was developed for aggregated local fault sources for the combined interpretations of all the seismic source characterization teams (CRWMS M&O 1998 [DIRS 103731], Figure 4-74). In characterizing local fault sources, each team addressed faults within about 20 km of Yucca Mountain (CRWMS M&O 1998 [DIRS 103731], Appendix E). Thus, this recurrence relation includes contributions from the Solitario Canyon, Windy Wash, Bow Ridge, Paintbrush Canyon, Stagecoach Road, Bare Mountain, and other local faults. For moment magnitudes of 6.0 and 6.5, consistent with events considered in the extreme-stress-drop approach to ground motion conditioning, the mean annual frequencies from this aggregate recurrence relation are approximately 1.3×10^{-4} and 5.0×10^{-5}, respectively.

For the observed distribution of earthquake stress parameters, a lognormal distribution with a median value of 30 bars and a lognormal standard deviation of 0.6 is used. The median value of 30 bars for point-source stress parameter is consistent with a static stress drop of about 30 bars that, for a circular fault rupture, is implied by the moment magnitude-rupture area relations of Wells and Coppersmith (1994 [DIRS 107201], Table 2A). Taking static stress drop as lognormally distributed, a median value of about 30 bars for static stress drop is also obtained using the database of earthquake information developed for the Next Generation of Ground-Motion Attenuation Models (NGA) project (public version 7.3, 02-14-06, http://peer.berkeley.edu/nga/flatfile.html) (Chiou et al. 2008 [DIRS 186319]).

Considering a median stress parameter of 30 bars with a lognormal standard deviation of 0.6, the values used to represent the probability distribution for extreme stress parameter (i.e., 150, 400, and 1100 bars; SNL 2009 [DIRS 185977], Section 5.4) have probabilities of exceedance of about 4×10^{-3}, 8×10^{-6}, and 10^{-9}, respectively. As an extreme-stress-parameter earthquake is conditional on an earthquake occurring, using the recurrence data for an M 6.5 earthquake on a local fault ($5.0 \times 10^{-5)}$ gives combined annual probabilities of exceedance of about 2×10^{-7}, 4×10^{-10}, and 5×10^{-14}, respectively. Thus, the median (400 bars) and high (1100 bars) values used to represent the extreme-stress-parameter distribution have probabilities of exceedance lower than need to be considered for FEP evaluation. Using the same distribution parameters (30 bars, lognormal standard deviation of 0.6), a stress parameter of about 250 bars, conditional on an earthquake occurring on a local fault, has a probability of exceedance of about 10^{-8}. Adopting an equivalency between the value of stress parameter and static stress drop, 250 bars is the static stress drop that needs to be considered in evaluating earthquake-induced water table rise. For the Kemeny and Cook model, using a value of 250 bars for static stress drop and 12 km for the vertical extent of faulting gives a bounding water table rise of 36 m.

In addition to maximum magnitude events, smaller, more frequent earthquakes may also affect the water table elevation. Assuming the smaller **M** earthquakes on local faults in the vicinity of Yucca Mountain affect the water table at the site, point-source stress parameters are determined based on a lognormal distribution with a median of 30 bars and a lognormal standard deviation of 0.6, such that, when combined with the aggregate recurrence rate for a given **M** for local faults, the combined probability of exceedance is about equal to or less than 10^{-8}. For this evaluation, the vertical extent of rupture is computed from an empirical relation between the logarithm of rupture width and moment magnitude (Wells and Coppersmith 1994 [DIRS 107201], Table 2A). The Wells and Coppersmith regression based on normal faulting events is used. A fault dip of 60 degrees is assumed to convert down-dip rupture width to vertical extent of rupture. Results are summarized in Table 1.2.10.01.0A-1[a].

Table 1.2.10.01.0A-1[a]. Earthquake-Induced Water Table Rise as a Function of Moment Magnitude and Vertical Extent of Faulting

Moment Magnitude	Annual Frequency[a]	Point-Source Stress Parameter with a Probability of Exceedance of 10^{-8} (bars)[b]	Static Stress Drop with a Probability of Exceedance of 10^{-8} (bars)[c]	Vertical Extent of Faulting (km)[d]	Water Table Rise (m)
5.50	4.0×10^{-4}	350	350	5	21
6.00	1.3×10^{-4}	290	290	8	28
6.50	5.0×10^{-5}	250	250	12	36
6.75	2.0×10^{-5}	220	220	14	37
7.00	5.0×10^{-6}	170	170	15	31

[a] Annual Frequency is for local faults in the vicinity of Yucca Mountain and is determined from CRWMS M&O 1998 [DIRS 103731], Figure 4-74.

[b] Point-source stress parameter with a probability of exceedance of 10^{-8} is determined using a lognormal distribution with a median of 30 bars and a lognormal standard deviation of 0.6.

[c] Static Stress Drop is taken as equal to the value of point-source stress parameter that has about an 10^{-8} mean annual probability of exceedance.

[d] Vertical Extent of Faulting is computed using the Wells and Coppersmith 1994 [DIRS 107201], Table 2A empirical relation between the logarithm of rupture width (RW) in kilometers and moment magnitude (**M**). The relation based on normal faulting events is used: log (RW) = −1.14 + 0.35 **M**. A fault dip of 60 degrees is used to compute vertical extent of faulting from down-dip rupture width.

Based on the above evaluation, earthquake-induced water table rise consistent with stress parameters having a mean annual probability of exceedance greater than 10^{-8} is about 40 m or less. A rise of the water table by this amount leaves a distance of about 147 m between the water table and the emplacement drift with the lowest elevation. This result supports exclusion of earthquake-induced water table rise from the TSPA.

Observations of Hydrologic Response to Seismic Activity Since the National Research Council Evaluation. A review of literature since 1992 indicates that dislocation model predictions of strain caused by fault displacement during earthquakes can reasonably explain observations of zones of bulk rock compression and dilation. In addition, this same research indicates that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected given the poroelastic theory, although exceptions to this observation are known and reflect the many competing factors that affect the direction of water level change at any particular well in an area. Literature evaluating coseismic poroelastic deformation and associated water level changes are summarized by Roeloffs (1996 [DIRS 186290]) and Manga and Wang (2007 [DIRS 186289]). Representative cases are briefly described below.

Earthquakes in June 2000 along two right-lateral strike-slip faults in southern Iceland exhibit coseismic deformation consistent with a dislocation model, with upward ground movement associated with coseismic extension zones northeast and southwest of the fault and downward ground movement associated with coseismic compression zones northwest and southeast of the fault (Jonsson et al 2003 [DIRS 186291], Figure 2). In addition, predicted coseismic pore-pressure response was shown to reasonably reproduce the observed water level changes in nearby geothermal wells, with areas of water level rise being associated with zones of compression and water level decline being associated with zones of dilation (Jonsson et al. 2003 [DIRS 186291], Figure 3).

A fault model of coseismic strain associated with fault displacement was shown to reasonably correlate to observed groundwater level changes associated with the 2003 Tokachi-oki earthquake. Water level changes in wells in areas of predicted dilation were observed to decrease, while water level changes in wells in areas of predicted contraction were observed to generally increase (Sato et al. 2004 [DIRS 186293], Figure 1).

Observations of step-like coseismic groundwater level changes in confined aquifers were also explained as the poroelastic response to static strains caused by the 1994 earthquake near Parkfield, California (Quilty and Roeloffs 1997 [DIRS 186478]). These authors concluded that the strains predicted by a dislocation model of the rupture were in good agreement with the changes in most of the wells.

Similarly, in an analysis of water level responses following an earthquake at Roermond, Netherlands, it was observed that the water-level response was in general agreement with the expected poroelastic response to volume strains (compression or dilation) predicted by a dislocation model of the event, with 16 of 19 wells with rising water levels corresponding to areas of compression and 7 of 9 wells with water level drops corresponding to areas of dilation,

although the magnitudes and durations were larger than expected (Grecksch et al. 1999 [DIRS 186477]).

The above examples indicate that, since the completion of the National Research Council panel report, scientific evidence supports the conclusion that poroelastic strains induced by faulting are reasonably predicted using a dislocation model. The strains are spatially variable and can be either compression or dilation of the rock mass associated with the event. The strains predicted from a dislocation model are able, in many cases, to explain observed water level responses in confined aquifers.

Earthquake-induced Response of Groundwater Level in Wells versus Response of Water Table Elevation. Observations of water level responses that are interpreted to result from earthquake-induced poroelastic deformation generally are from open boreholes where these water level responses reflect the change in pore pressure associated with the deformation. Groundwater level changes may be associated with changes in hydraulic head when the well is open to a confined aquifer(s) or to water table elevation changes when the well is open to an unconfined aquifer. When wells are open to multiple aquifers, the water level in the well will be controlled by the hydraulic head in the most transmissive unit(s) intersecting the well.

Observed water level responses discussed above are generally for confined aquifers. Although researchers have not focused on water level responses in comparison to water table responses, the available information supports the conclusion that water table responses are generally much less (in several cases an order of magnitude less) than water level responses.

Coseismic water level responses in wells completed in confined aquifers following the 1999 **M** 7.5 Chi-Chi earthquake in Taiwan were observed to range from less than 1 m to more than 5 m, while water level changes in the uppermost unconfined aquifer were shown to be much smaller (ranging from 0 to 0.5 m) (Manga and Wang 2007 [DIRS 186289], p. 302). In addition, most of the observed water level changes in wells completed in confined aquifers following the 2003 Tokachi-oki **M** 8.0 earthquake in Japan could be explained by the poroelastic response and volumetric strain derived from a fault dislocation model, while an earlier earthquake in the same area had responses that could not be explained by poroelastic response because it included responses of unconfined aquifers, which are not highly sensitive to volumetric strain changes (Koizumi et al. 2005 [DIRS 186295]).

The reason for the greater amplitude of response of the water level in confined aquifers is the result of the smaller storativity of confined aquifers. Considering a given poroelastic compression with the resultant volume of water released per unit surface area of the aquifer, the smaller storativity of the confined aquifer will result in a higher water level rise in boreholes that are open to the confined aquifer. In the vicinity of Yucca Mountain, the Death Valley Regional Groundwater Flow Model has estimated the specific storage of confined aquifers of between 10^{-7} and 10^{-4} m^{-1} and a specific yield of unconfined aquifers of about 0.1 (Belcher 2004 [DIRS 173179], Figure F-38). Considering confined aquifer thicknesses of about 10^{2} m implies a storativity of between about 10^{-5} and 10^{-2}, a factor of 10^{4} to 10^{1} less than the specific yield of the unconfined aquifers. Therefore, an earthquake capable of causing a water level rise of 10 m in the confined aquifers at Yucca Mountain would be expected to cause only a 1.0 to 0.001 m rise in the water table.

The distinction between water level rise and water table rise becomes relevant when confining units separate the aquifers. If there are no confining units, the water table response will be equal to the water level response to the poroelastic deformation, although the time it takes to propagate from the deeper zones to shallower water table is a function of the vertical hydraulic diffusivity of the rock mass (Roeloffs 1996 [DIRS 186290], p. 167). Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]), in reducing the coupled hydro-mechanical response to a simplified mechanical representation, assumed no confining units and that hydraulic head changes at depth instantaneously propagated to water table elevation changes. In assuming there were no confining units, Kemeny and Cook (1992 [DIRS 100989]) effectively assumed that the water volume released by the compression of the entire saturated thickness of rock (about 10,000 m) became available for raising the water table. While this assumption is consistent with development of a bounding model, observations of water level and water table elevation changes noted above, combined with the known confining units in the saturated zone in the vicinity of Yucca Mountain, indicate this assumption results in an overestimation of realistic water table rise values.

Possible Earthquake-Induced Water Table Fluctuations in the Vicinity of Yucca Mountain. The historical record of water table elevations in the vicinity of Yucca Mountain shows no evidence of past significant rises in the water table associated with seismic events. The observed indicators of previous higher water table elevations and spring discharge elevations are very well correlated with times of previous wetter climates; there is no indication of higher water levels that cannot be reasonably explained by the local effects of a wetter climate. However, water table rises associated with poroelastic deformation due to fault displacement are generally short lived (time periods of months), so observations of such water table rises would not be expected in the geologic record.

Large excursions in the water table resulting from earthquakes in the geologic past could have left evidence of their occurrence in the form of secondary mineral veins. However, multiple lines of evidence from shallow vein minerals and from the deeper unsaturated zone do not indicate that such minerals precipitated from upwelling groundwater from the saturated zone.

There is no evidence from the isotopic geochemistry of shallow calcite veins for large-scale rise in the water table near Yucca Mountain in the geologic past. Stable isotopes of carbon and oxygen from groundwater and calcite veins at Trench 14 and Busted Butte indicate that the calcite could not have precipitated from saturated zone groundwater (National Research Council 1992 [DIRS 105162], Appendix A). Overlap in the carbon and oxygen isotopic compositions of vein calcites and calcite from soils suggest that shallow vein calcites are pedogenic in origin and precipitated from downward percolating infiltration. Differences in the uranium activity ratios in groundwater and shallow calcite veins also preclude upwelling groundwater as the source of these calcite veins. Similarly, discrepancies in the strontium isotopic composition of groundwater and the shallow calcite veins show that this calcite did not precipitate from groundwater in the saturated zone (National Research Council 1992 [DIRS 105162], Appendix A). The National Research Council study concluded (National Research Council 1992 [DIRS 105162], p. 134):

> …the isotopic evidence now available indicates that no prolonged excursion of the water table above its present level has occurred in the last ca. 100 ka.

There is also no evidence of upwelling groundwater from the saturated zone, for at least the last several million years, based on the stable isotopic geochemistry, fluid inclusions, and texture/morphology of secondary calcite and silica from the Exploratory Studies Facility. The carbon and oxygen isotopic compositions of late-stage calcite from the unsaturated zone show little overlap with the range of compositions that could have formed by precipitation from groundwater in the upper saturated zone (National Research Council 1992 [DIRS 105162], Appendix A). Temperatures at the repository horizon have not been impacted by upward flow of warmer groundwater from the saturated zone over the past several million years. Data from fluid inclusion assemblages and integrated uranium-lead age dating from secondary minerals indicate that ambient temperatures have prevailed for approximately the past two to five millions years (Wilson et al. 2003 [DIRS 163589]; Whelan et al. 2008 [DIRS 185452]). Textural and physical evidence indicate that secondary calcite and opal coatings formed under unsaturated flow conditions with slow, uniform growth rates (Paces et al. 2001 [DIRS 156507]).

Observed Earthquake-induced Water Level fluctuations in the Vicinity of Yucca Mountain. Water levels in wells in the vicinity of Yucca Mountain have been observed to change due to coseismic deformation (compression or dilation) associated with nearby earthquakes. Of principal note are the water level responses observed following the June 1992 earthquakes at Landers, California (a **M** 7.6 earthquake that occurred on June 28, 1992, about 300 km southwest of Yucca Mountain), Big Bear Lake, California (a **M** 6.6 earthquake that also occurred on June 28, 1992, about 300 km southwest of Yucca Mountain) and Little Skull Mountain, Nevada (a **M** 5.6 earthquake that occurred on June 29, 1992, about 23 km from Yucca Mountain), and the October 1999 earthquake at Hector Mine, California (a **M** 7.1 about 20 km to the northeast of the Landers earthquake). Short-term fluid pressure oscillations in wells USW H-5 and H-6 associated with the passing seismic waves of the June 1992 earthquakes are illustrated and discussed by O'Brien (1993 [DIRS 101276]; DTN: GS930108312312.003 [DIRS 171974]). In addition, water level offsets, believed to be due to poroelastic deformation of the rock mass, in wells UE-25p#1 and USW H-3 are illustrated in the report by O'Brien (1993 [DIRS 101276]), with a decline of about 50 cm in UE-25p#1 (completed in the confined lower carbonate aquifer) and an increase of 28 cm in USW H-3 (completed in a confined tuff aquifer). The location of these and other observation wells discussed below are identified in *Water-Level Data Analysis for the Saturated Zone Site-Scale Flow and Transport Model* (BSC 2004 [DIRS 170009], Figure 1-2). Similar water level offset observations are observed for well AD-4a (with a water level rise of about 3 ft for the Landers/Little Skull Mountain earthquakes and also about 3 ft for the Hector Mine earthquake). In addition, analyses of water level changes at Devils Hole indicate about a 0.1 to 0.04 m decline following the Landers/Little Skull Mountain and Hector Mine earthquakes, respectively (Cutillo and Ge 2006 [DIRS 186288], Figure 3).

With the exception of the above Devils Hole observations (which indicate a decline in the water table surface following the earthquake), the other observations of water level fluctuations are within confined aquifers. Due to the low storativity of the confined aquifers, it is expected that observation wells, piezometers, or pressure transducers that are measuring water level changes in these confined aquifers would represent a change that is not reflective of the change in the water

table surface, due to the large specific yield of the water table aquifer. To evaluate this, the National Water Information System of the U.S. Geological Survey database of groundwater levels in the vicinity of Yucca Mountain was searched for wells with recorded water levels around the time preceding and immediately following the June 1992 earthquakes. The following observation wells, which are wells that intercept the water table, indicate no discernible change due to these earthquakes: UE-25 WT-17, UE-25 WT-16, USW WT-10, UE-25 WT-14, UE-25 WT-13, USW WT-7, USW WT-1, J-13, and J-12. Well UE-25 WT-4 had about a 1 ft water level increase that quickly dissipated and may even have been an anomalous reading as the data are indicated as being provisional and subject to revision. Well UE-25 WT-6 had about a 3.5 ft increase followed by a decline over about 3 months to a water level that is about 2 ft below the static level before the earthquake. The anomalous behavior at well UE-25 WT-6 may be due to vertical and lateral confinement of this zone which is completed in the low permeability confining unit. Regardless of the explanation of the anomalous behavior at well UE-25 WT-6, the water table response is significantly less than the response in confined aquifers in the area due to the same seismic event. This observation is expected and is consistent with the larger storage in the unconfined aquifers as opposed to the low storativity in the confined aquifers. It reinforces the previously noted general observations that water level responses of the water table are much less than the water level response in wells or piezometers open to confined aquifers.

Implications of Recent Observations of Earthquake-induced Hydrologic Response on the Conclusions of the National Research Council. Based on a review of observed coseismic water level and water table responses, it is concluded that the regional stress change model developed by Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]) and adopted by the National Research Council (1992 [DIRS 105162], Chapter 5), while bounding, results in a significant overestimation of the potential rise in the water table associated with earthquakes affecting Yucca Mountain. In particular, there are two principal areas in which the model is unrealistic and inconsistent with the expected water table response following an earthquake:

- The regional stress change model treats strains from normal faulting in an extensional tectonic regime as resulting in a uniform increase in compressive stress throughout the affected volume of rock. Observations since the model was developed and used by Kemeny and Cook and the National Research Council indicate that strains vary spatially and are well predicted by the dislocation model. Predictions of water table rise based on the regional stress change model, therefore, are overestimated, in part because of the unrealistic characterization of earthquake-induced strain.

- Water table response due to the earthquake-induced uniform compressive strain assumed in the regional stress change model is assumed to lead to uniform pore pressure changes that are immediately propagated vertically through the hydrostratigraphic column with a resultant immediate displacement of the water table surface into the available empty pore space above the water table. In addition to ignoring flow in directions other than vertical, which would result from a more realistic characterization of earthquake-induced strains, this assumption also leads to overestimation of water table rise by not taking into account the effect of confining units, which are known to exist in the Yucca Mountain vicinity.

As a result, estimates of potential water table rises based on the Kemeny and Cook regional stress change model, while bounding, significantly overstate the potential and amplitude of a

seismically induced water table rise. In light of this conclusion, the results of the National Research Council Panel, analyses of water-table-rise implications from PSHA results and extreme ground motion conditioning, and observed earthquake-induced hydrologic responses, both in the vicinity of Yucca Mountain and worldwide, support a screening decision to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity), from the TSPA.

Additional Modeling since the National Research Council Evaluation. Gauthier et al. (1996 [DIRS 100447], pp. 163 to 164) expanded on the work of Carrigan et al. (1991 [DIRS 100967]) and Bredehoeft (1992 [DIRS 101122]) using the dislocation model. For the flow part of the problem, they used a dual-permeability formulation involving both fracture and matrix flow. They considered three different fault types: normal, listric, and strike-slip. For all three fault types, an earthquake with a 1-m displacement and 30-km rupture length was modeled. For the normal and strike-slip cases, the vertical extent of faulting was 10 km; for the listric case the vertical extent of faulting was 2 km. The greatest response was found for the strike-slip case in which complete saturation of fractures occurs within 1 hour to an elevation of 50 m above the steady-state water table, but drops to 10% saturation after 20 hr. Matrix saturations change little. Smaller rises were obtained for the normal- and listric-faulting cases. The simulated system returned to steady-state conditions within six months.

Seismic Effects on the Large Hydraulic Gradient North of the Repository

Another aspect of the water table rise issue concerns the large hydraulic gradient of up to 0.13 just to the north of the repository (SNL 2007 [DIRS 177391], Section 6.3.1.4). The water table elevation increases from south to north as one moves away from the repository. If this gradient were to migrate southward, the resulting water table below the repository could be much higher than present-day conditions.

Davies and Archambeau (1997 [DIRS 103180], p. 28) hypothesize that the large hydraulic gradient is a result of residual stress effects in the rock induced by the Timber Mountain caldera. Furthermore, the authors suggest that moderate earthquakes in this area could induce a sufficient change in geomechanical strain downstream of the current large hydraulic gradient to induce a similar gradient downstream of the repository. This would result in a large (150 m to 250 m) rise in the water table beneath the repository. However, the hypothesized residual stress effects of the 10-Ma Timber Mountain caldera are inconsistent with stress measurements at Yucca Mountain that show consistency with stress indicators elsewhere at the Nevada Test Site (Stock et al. 1985 [DIRS 101027], Stock and Healy 1988 [DIRS 101022]). Stress indicators for the Nevada Test Site are derived from hydraulic fracturing, overcoring, earthquake focal mechanisms, borehole breakouts, orientations of explosion-produced fractures, and study of Quaternary faults and cinder-cone alignments (Stock et al. 1985 [DIRS 101027], Tables 1 and 3, Figure 11; Stock and Healy 1988 [DIRS 101022], Table 6-1). These studies show a reasonably uniform direction of extension between northwest and west, with a mixed potential-slip regime of normal faulting (mainly for shallow indicators) and strike-slip faulting (mainly for deep indicators). Also, stress measurements in borehole USW G-2, north of the gradient, are within the same (“combined normal and strike-slip”) faulting regime as that indicated by the results from the three holes south of the large gradient (USW G-1, USW G-3, and UE-25 p#1). Based on the stress measurements in the four holes, the tendency for strike-slip faulting is greatest in

the southeastern hole, UE-25 p#1, not in the northern Yucca Mountain area where USW G-2 is located, as Davies and Archambeau (1997 [DIRS 103180]) propose.

Stress measurements are also available from the ESF. Results from hydraulic fracturing experiments in two boreholes in the Thermal Test Facility alcove and one borehole in the Northern Ghost Dance Fault alcove indicate a west-northwest extensional stress regime. The relative magnitudes of the principal stresses are consistent with potential normal faulting (SNL 1996 [DIRS 163645]; DTNs: SN0308F3710195.003 [DIRS 166458] and SNF37100195002.001 [DIRS 131356]).

Principal stress orientations inferred from earthquake focal mechanism studies also indicate a west-northwesterly directed least principal stress. Observed focal mechanisms exhibit a mixture of normal and strike-slip faulting. The overall data suggest a uniform stress regime in the vicinity of Yucca Mountain (von Seggern et al. 2001 [DIRS 156297], Section 9). Available data do not support a residual stress effect from the Timber Mountain caldera, do not support a modern stress field changing from strike-slip in northern Yucca Mountain to normal south of the large hydraulic gradient, and do not support a southward decrease of the least principal stress. Based on these findings, any changes in stress resulting from seismic activity would be expected to have a negligible effect on the location of the large hydraulic gradient. Therefore, migration of the large hydraulic gradient as a result of seismic activity is excluded from TSPA on the basis of low consequence.

Seismic Effects on Saturated Zone Groundwater Chemistry

The effect of a seismically induced hydrologic response on saturated zone groundwater chemistry will be insignificant. Groundwater isotopic and geochemical signatures within the Yucca Mountain region are indicative of groundwater flow directions and flow paths that have existed over the past 10,000 years. Uncorrected groundwater ages determined from ^{14}C (percent modern carbon) data (SNL 2007 [DIRS 177391], Table A6-7 and Section B7) and an exponential decay relationship (SNL 2007 [DIRS 177391], Equation A6-3) range from about 12,000 to 18,000 years old in the vicinity of Yucca Mountain. The analysis of the geochemistry supports the conclusion that the bulk of the groundwater beneath Yucca Mountain is derived from local recharge (SNL 2007 [DIRS 177391], Sections A6.3.6.3 and A6.3.6.4). Therefore, the saturated zone groundwater under the repository and along the saturated zone transport path is primarily paleoclimate recharge water with a small component (2% to 15%) of young water less than 1,000 years old (SNL 2007 [DIRS 177391], Table A6-8). Given that the saturated zone groundwater below the repository comes from local recharge through the unsaturated zone, any saturated zone water that is temporarily forced into the unsaturated zone by seismic activity would be expected to have a negligible effect on chemical composition or temperature relative to natural variations.

For the unsaturated zone, the range of water compositions that is used to define radionuclide sorption coefficients is taken from the range of water compositions found in the unsaturated zone and saturated zone (SNL 2007 [DIRS 177396], Appendix A, Section A4). Therefore, any alteration of composition through mixing of unsaturated zone and saturated zone waters as a result of water table rise is expected to lie within the range of uncertainty for groundwater composition already included in the TSPA. For the unsaturated zone, any effects of water table

rise are expected to have a negligible effect on temperature in comparison with the effects of repository heating, which is excluded in terms of unsaturated zone flow and transport in excluded FEPs 2.2.10.01.0A (Repository-Induced Thermal Effects on Flow in the UZ) and 2.2.10.06.0A (Thermo-Chemical Alteration in the UZ (Solubility, Speciation, Phase Changes, Precipitation/Dissolution)).

Summary

The distance between the elevation of the water table and the lowest waste emplacement drift is about 187 m for both present and future, wetter climates. Multiple lines of evidence indicate that earthquake-induced rises in the water table will be insufficient to eliminate that gap:

- A National Research Council Panel, asked to evaluate the evidence for past earthquake-induced water table rise and the possibility of future earthquake-induced water table rise, concluded that such an effect is unlikely to exceed 50 m over the next 10,000 years.

- Even when a bounding model of water table rise (Kemeny and Cook 1990 [DIRS 129658], 1992 [DIRS 100989]) is used, almost all fault cases defined as part of the PSHA seismic source characterization activity result in calculated water table rise values less than 187 m.

- Even when a bounding model of water table rise (Kemeny and Cook 1990 [DIRS 129658], 1992 [DIRS 100989]) is used, PSHA seismic source characterization and fault displacement hazard results with a 10^{-8} mean annual probability of being exceeded lead to water table rise values of 122 m or less. This leaves a gap between the water table and the lowest waste emplacement drift of at least 65 m.

- Using a bounding model of water table rise (Kemeny and Cook 1990 [DIRS 129658], 1992 [DIRS 100989]), given the recurrence of earthquakes on local faults in the vicinity of Yucca Mountain, point-source stress parameter values yielding a combined probability of exceedance of 10^{-8} lead to water table rise values of less than about 40 m (i.e., a remaining gap of 147 m or more).

- Worldwide observations of sustained hydrologic effects related to earthquakes are generally consistent with a dislocation approach to modeling the poroelastic response of the earth's crust. A regional stress change approach, which Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]) combined with conservative assumptions to create a simple bounding model of water table rise, significantly overestimates water table rise because some assumptions, while bounding, are unrealistic.

- Stress measurements in the vicinity of Yucca Mountain are consistent with those for the vicinity of the Nevada Test Site and do not support a residual stress effect from the Timber Mountain caldera that might lead to southward movement of the large hydraulic gradient north of the repository in response to a future earthquake.

Also, the direct effects of seismic activity on the elevation of the water table are short-lived with respect to performance periods of 10,000 and 1,000,000 years.

As a result, groundwater flow and radionuclide transport would not be significantly affected by the hydrologic effects of future seismic activity, and therefore the hydrologic response to seismic activity is excluded from the TSPA on the basis of low consequence.

The effects of seismic activity on groundwater chemistry and temperature are also excluded from the TSPA on the basis of low consequence, because the changes in temperature caused by seismicity will be negligible compared to changes resulting from other natural variations in temperature or through repository heating. Changes in geochemical conditions will also be negligible in terms of the uncertainties in water chemistry already included in the unsaturated zone and saturated zone models used in TSPA.

Based on the previous discussion, omission of FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity) will not result in a significant adverse change in the magnitude or timing of either radiological exposure to the RMEI or radionuclide releases to the accessible environment. Therefore, this FEP is excluded from the performance assessments conducted to demonstrate compliance with 10 CFR 63.311 and 63.321 and with 10 CFR 63.331 [DIRS 186479], on the basis of low consequence.

FEP: 2.1.03.04.0B

FEP NAME:

Hydride Cracking of Drip Shield

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*The Screening Justification is replaced by the following paragraphs:*]

The drip shield plates are to be fabricated from Titanium Grade 7, an α-titanium alloy, 15-mm thick (SNL 2007 [DIRS 179354], Table 4-2, Parameter Number 07-04). The drip shields are supported by Titanium Grade 29, an $\alpha + \beta$ titanium alloy, support beams (SNL 2007 [DIRS 179354], Table 4-2, Parameter Number 07-04). The Titanium Grade 29 drip shield support beams, which are external to the drip shield and exposed to seepage water and are more prone to hydrogen absorption than the crossmembers located on the underside of the drip shield (SNL 2007 [DIRS 179354], Table 4-2). Failure of the drip shields due to general corrosion is discussed in included FEP 2.1.03.01.0B (General Corrosion of Drip Shields).

Hydrogen absorption in α-titanium and $\alpha - \beta$ titanium alloys can occur when three general conditions are simultaneously met (Covington 1979 [DIRS 151097], pp. 378 to 381; Schutz and Thomas 1987 [DIRS 144302], p. 673; SNL 2007 [DIRS 181339], Section 6.1.2):

(1) A mechanism exists for generating nascent (atomic) hydrogen on the surface (e.g., the water reduction reaction is a thermodynamically viable cathodic reaction).

(2) The temperature of the drip shield is above approximately 80°C (175°F) such that a surface film of hydride is not formed and the diffusion rate of hydrogen into α-titanium is significant.

(3) Either (a) the solution pH is less than 3 or greater than 12, or (b) impressed potentials are sufficiently cathodic to induce the redox transformation of Ti^{4+} to Ti^{3+}within the passive TiO_2 oxide (approximately −0.7 V versus the saturated calomel reference electrode under near neutral conditions).

By assuming that the only viable cathodic reaction on the titanium surface is the water reduction reaction, condition (1) is always met as long as aqueous corrosion occurs. At certain repository locations, where temperatures are greater than or equal to 80°C (175°F) and concentrated groundwater is present, conditions (2) and (3) may also be satisfied. However, it should be noted that while the aforementioned three conditions are necessary requirements for hydrogen

absorption, they are not sufficient in determining if hydrogen embrittelment will take place. A critical hydrogen concentration within the metal must be achieved in order to reduce the mechanical properties to the extent that hydrogen-induced cracking can occur (SNL 2007 [DIRS 181339], Section 8). It should also be noted that given the oxic conditions that will prevail within any given drift, the assumption that the cathodic current density is solely due to the water reduction reaction will consistently overestimate the hydrogen production rate as the oxygen reduction reaction, the expected cathodic reaction, is assumed not to occur.

The term hydrogen embrittlement is used to refer to the deleterious impact of hydrogen on the mechanical properties of a material. Hydrogen-induced cracking results from the combined action of hydrogen and residual or sustained applied tensile stresses, whereby crack initiation and/or propagation occur at lower stress levels than in the absence of absorbed hydrogen. The critical hydrogen concentration of Titanium Grade 7 is estimated as 1,000 ppm (μg/g) (SNL 2007 [DIRS 181339], Section 5.2). The critical hydrogen concentration of Titanium Grade 29 is estimated at between 400 and 600 ppm (μg/g) (SNL 2007 [DIRS 181339], Section 5.2[a]). The value of f_h, fractional hydrogen absorption efficiency, is conservatively selected as 0.015 (SNL 2007 [DIRS 181339], Sections 8.1 and 8.3.2). By using the 2.5-year general corrosion rates obtained for Titanium Grade 7 obtained at the LTCTF, the 0.999 probability value from the upper 97.5% uncertainty bound general corrosion rate of Titanium Grade 7 in the aggressive environment (90°C SCW) is about 58 nm/yr (SNL 2007 [DIRS 181339], Table 4-1[a]). At 10,000 years, the hydrogen pickup of the Titanium Grade 7 drip shield plate material calculated is 105 μg/g (SNL 2007 [DIRS 181339], Section 8[a] and Table 8-1[a]). Given that the maximum initial hydrogen content in Titanium Grade 7 is 150 μg/g (SNL 2007 [DIRS 181339], Table 4-2[a]), the estimated maximum total hydrogen content in the drip shield plate material at 10,000 years is 255 μg/g, which is well below the critical hydrogen concentration for Titanium Grade 7.

Because no long-term data from the LTCTF are available for general corrosion rate of Titanium Grade 29 in repository-relevant environments, the Titanium Grade 29 general corrosion rate is calculated from conversion factors based upon short-term experiments as discussed in *General and Localized Corrosion of the Drip Shield* (SNL 2007 [DIRS 180778], Section 6.2.2[a]). By using the Titanium Grade 29/Titanium Grade 7 corrosion rate ratio multiplier values, the absorbed hydrogen concentrations in Titanium Grade 29 drip shield support beam material are calculated in *Hydrogen-Induced Cracking of the Drip Shield* (SNL 2007 [DIRS 181339], Section 6.2[a]). Using the 75th percentile multiplier and the 0.999 probability value from the upper 97.5% uncertainty bound of the Titanium Grade 7 general corrosion rate in the specified aggressive environment, at 10,000 years, the hydrogen pickup in the drip shield structural support material (Titanium Grade 29) is 84 μg/g. Given that the maximum initial hydrogen content in Titanium Grade 29 is 150 μg/g (SNL 2007 [DIRS 181339], Table 4-2[a]), the estimated maximum total hydrogen content in the drip shield structural support material at 10,000 years is 234 μg/g. Using the 95th percentile multiplier and the 0.999 probability value from the upper 97.5% uncertainty bound of the Titanium Grade 7 general corrosion rate in the specified aggressive environment, at 10,000 years, the hydrogen pickup in the drip shield structural support material (Titanium Grade 29) is 191 μg/g, yielding an estimated maximum total hydrogen content at 10,000 years of 341 μg/g. These conservatively calculated hydrogen content values are below the critical hydrogen concentrations for Titanium Grade 29 (400 to 600 ppm) (SNL 2007 [DIRS 181339], Section 8.1[a] and Table 8 2[a]).

The locally hydrided regions that may potentially result from galvanic effects (e.g., from failed rock bolts or ground supports contacting the drip shield surface) will not be sufficiently large in magnitude such that they result in hydrogen-induced cracking as illustrated in *Hydrogen-Induced Cracking of the Drip Shield* (SNL 2007 [DIRS 181339], Section 6.3.2). The rationale presented in the reference includes the following points: (1) the contact area is small and has a low anode-to-cathode area ratio, (2) the presence of seepage is anticipated to be intermittent at temperatures greater than or equal to 80°C (175°F), (3) sustaining the water reduction reaction under the repository conditions is unexpected, and (4) the titanium drip shield and the steel component surfaces that may contact it will experience a long period of dry conditions where the temperature is greater than or equal to 85°C (185°F), resulting in the formation of a thermal oxide, in effect passivating both materials, thereby minimizing any potential galvanic interactions and preventing increased hydrogen absorption.

When a titanium alloy containing an appreciable concentration of aluminum (e.g., Titanium Grade 29) is welded with an aluminum-free alloy (e.g., Titanium Grade 7), an abrupt concentration gradient of aluminum is formed at the weld fusion line. This concentration gradient has been found to drive uphill diffusion of hydrogen from the aluminum-rich material to the aluminum-poor material, resulting in the formation of hydride bands along the weld fusion line, increasing the susceptibility of the weld region to hydrogen embrittlement (SNL 2007 [DIRS 181339], Section 6.3[a]). To eliminate the potential for hydride band formation due to hydrogen redistribution, the weld filler metal utilized will be Titanium Grade 28 (SNL 2007 [DIRS 179354], Table 4-2; SNL 2007 [DIRS 181339], Section 6.3[a]). That is, welds made between Titanium Grade 7 plates and Titanium Grade 29 support beams will be conducted utilizing Titanium Grade 28 filler material. Titanium Grade 28 has an aluminum content of 2.5% to 3.5%, providing an intermediate level between the Titanium Grade 7 plates and Titanium Grade 29 support beams. As a result, the abrupt aluminum concentration gradient that has been found to result in hydrogen redistribution and the enhanced hydride formation can take place when high aluminum alloys are welded with a low aluminum filler metal is avoided (SNL 2007 [DIRS 181339], Section 6.3[a]; Kennedy 1993 [DIRS 177388]).

Based on the previous discussion, FEP 2.1.03.04.0B (Hydride Cracking of Drip Shields) is excluded from the performance assessments conducted to demonstrate compliance with 10 CFR 63.311, 63.321, and 63.331 [DIRS 186479], on the basis of low probability.

TSPA DISPOSITION:

[*No modification to the parent report, except the second paragraph is changed as follows:*]

The sorption calculations for iron oxyhydroxide colloids are based on a mechanistic surface complexation-based competitive sorption model, where the sorption coefficients are calculated as a function of dissolved concentration of competing species, pCO_2, and sorption sites (SNL 2007 [DIRS 177407], Sections 6.3.4.2.3 and 6.5.2.4). The results of these calculations are implemented in TSPA by applying reversible sorption of thorium, uranium, and neptunium on iron oxyhydroxide colloids by computing an effective K_d at each timestep. The sorption of plutonium and americium on iron oxyhydroxide colloids is modeled as a kinetic sorption process by applying a forward rate constant as described in *Waste Form and In-Drift Colloids-Associated Radionuclide Concentrations: Abstraction and Summary* (SNL 2007 [DIRS 177423], Section 6.3.12.2).

[a] "Infinite" means that an infinite amount of fissile waste released in this model will not produce an arrangement that can reach the critical limit.

FEP: 2.2.06.01.0A

FEP NAME:

Seismic Activity Changes Porosity and Permeability of Rock

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*The Screening Justification is replaced by the following paragraphs:*]

Plate tectonic activity has imparted crustal extension stresses within the Basin and Range Province (which includes the Yucca Mountain region) during the past 12 million years. The height of this activity occurred between 10 and 12 million years ago, with estimated extension rates ranging between 10 and 30 mm per year (National Research Council 1992 [DIRS 105162], Chapter 2). During this period, major faults and fractures were created in the vicinity of Yucca Mountain. Approximately 5 million years ago, regional extension rates declined to 5 to 10 mm per year. At present, extension rates are still in a declining state (National Research Council 1992 [DIRS 105162], Chapter 2).

Regional extension imparts local extensional, compressional, and/or shear stresses on the crust, depending on location, depth, and the juxtaposition of parent rock units and existing faults and fractures. Release of stress results in seismic activity that creates faults (rupture), and causes fault displacement, vibratory motion, and/or spatial redistribution of stresses not associated with specific faults. Vibratory motion and spatial redistribution of stress in the rock matrix can alter the hydrologic properties of the parent rock by: (1) causing a change in pore pressure, or (2) causing dilation, compression, or breakage of granular structures in the rock, leading to corresponding changes in permeability.

Pore pressure changes associated with seismic events are addressed in detail under excluded FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity). The discussion is based in part on the results of an assessment conducted by the National Research Council (1992 [DIRS 105162], Chapter 5) that evaluated water table fluctuations for a large normal-faulting seismic event. It was concluded that a future seismic event would not alter the rock hydrologic properties on a regional scale.

Damage of the rock matrix material in lithophysal units due to seismic loading would manifest itself in the form of inter-lithophysal tensile fractures that coalesce to form observable shear fractures with offset. Such damage would indicate that seismically induced cyclic shear stresses had exceeded the shear-strain threshold to cause new fracturing. The shear-strain threshold is an uncertain parameter and thus is characterized as a probability distribution. The exposed

lithophysal rocks in the ESF and the ECRB Cross-Drift show no inter-lithophysal fracturing of this type. Observed fracturing is consistent with a typical cooling-fracture-related history (BSC 2005 [DIRS 170137], Section 6). These findings indicate that the matrix material is largely unaffected by redistribution of strain introduced by seismic activity over the more than 10 million years since the rocks were deposited.

Although there is no evidence that seismically related cyclic shear strains have exceeded the threshold required to produce additional fracturing of the rock at Yucca Mountain in the past about 10 million years, predicted shear strains for conditioned ground motions with mean annual probabilities of exceedance of 10^{-7} and 10^{-8} exceed the lower portion of the shear-strain-threshold distribution. If new fractures are generated by extreme seismic activity, however, their effect is addressed by a fracture sensitivity study (Appendix I) that forms part of the screening exclusion justification for FEPs 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults), and 2.2.06.02.0B (Seismic Activity Changes Porosity and Permeability of Fractures).

The generation of new fractures as a result of seismic activity is encompassed within the existing sensitivity analyses for changes in fracture properties. This may be seen through the cubic law used to estimate changes in fracture permeability, k, as a result of changes in the hydraulic fracture aperture, b:

$$k = \frac{f b^3}{12} \qquad \text{(Eq. 10[a])}$$

in which f is the is the fracture frequency. The hydraulic fracture aperture is also given by:

$$B = \frac{\beta \varphi}{f} \qquad \text{(Eq. 11[a])}$$

in which φ is the fracture porosity and β is a scale factor to account for constrictions affecting the hydraulic fracture aperture. For a given seismically-induced strain, ε, which is allocated to fractures, the fracture porosity increases to φ + ε. If the seismically induced strain is taken up entirely by the existing fractures, then the fracture aperture increases to:

$$\frac{\beta(\varphi+\varepsilon)}{f} \qquad \text{(Eq. 12[a])}$$

and the permeability is given by:

$$k = \frac{f\left(\frac{\beta(\varphi+\varepsilon)}{f}\right)^3}{12} = \frac{\beta^3(\varphi+\varepsilon)^3}{12\, f^2} \qquad \text{(Eq. 13[a])}$$

On the other hand, if new fractures are generated to absorb some of the seismically induced strain, then the fracture frequency increases to $\hat{f}$ and the new fracture permeability is given by:

$$k = \frac{\hat{f}\left(\frac{\beta(\varphi+\varepsilon)}{\hat{f}}\right)^3}{12} = \frac{\beta^3(\varphi+\varepsilon)^3}{12\, \hat{f}^2} \qquad \text{(Eq. 14[a])}$$

Because $\hat{f} > f$, the permeability of a system with seismically induced fractures is smaller than the permeability of a system in which the seismic strain is taken up entirely by the existing fractures. Therefore, the possibility of new fractures is included within the range of the existing sensitivity analyses. Other effects pertaining to induced fractures lead to increased fracture-matrix interface area and, therefore, increased fracture-matrix interaction. This results in improved performance with respect to damping of episodic flow and radionuclide transport rates as compared with the system without additional fractures. Thus, low-probability conditioned ground motions are adequately considered in excluding FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock), from the TSPA.

Given the relatively high strength of the matrix material and the extensive fracture network in the rock mass, the strain introduced by seismic activity might be accommodated by deformation of, and slip along, existing faults and fractures. The effects of seismic activity on the properties of faults and fractures are discussed under excluded FEP 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults), and excluded FEP 2.2.06.02.0B (Seismic Activity Changes Porosity and Permeability of Fractures). However, localized changes in hydrologic properties could occur adjacent to existing faults and fractures due to enhancement of brecciation and gouge zones and possibly due to the creation of new fractures outside of the brecciated zone. Based on data from the ESF, this disturbed rock zone, labeled herein as a "zone of alteration," is correlated with the amount of fault offset (Sweetkind et al. 1997 [DIRS 177047], p. 68). Faults with 1 to 5 m of cumulative offset have a zone of increased fracturing of only 1 to 2 m; faults with tens of meters of offset can have a zone of fracturing up to tens of meters wide (Sweetkind et al. 1997 [DIRS 177047], pp. 68 to 72). The hydrologic properties in the zone of alteration reflect the cumulative response of a dynamic seismic past, demonstrative of rapid extension rates in existence 10 to 12 million years ago and, to a lesser extent, the lower extension rates occurring today. In light of the cumulative nature of seismic processes at Yucca Mountain over more than 10 million years, any changes in hydrologic properties resulting from seismic activity over the 10,000-year to 1,000,000-year postclosure period are expected to be negligible.

The effects of a future seismic event on the hydrologic properties of the host rock are evaluated here based on the fault displacement hazard findings of the PSHA for Yucca Mountain (CRWMS M&O 1998 [DIRS 103731], Sections 4 and 8). The PSHA expert panel assessed the displacement hazard for intact host rock in the vicinity of the repository to be less than 0.1 cm for a 10^{-8} mean annual probability of exceedance (DTN: MO0401MWDRPSHA.000 [DIRS 185267], file: *s7d.frac_mean*; CRWMS M&O 1998 [DIRS 103731], Section 8.2.1). Consequently, the rock matrix is largely unaffected by strain redistribution caused by seismic activity and no significant new faults or fractures are likely to form in the Yucca Mountain vicinity within the next 10,000 to 1,000,000 years.

The small seismic displacement hazard for intact rock, less than 0.1 cm for a 10^{-8} mean annual probability of exceedance, corresponds to the level of displacement that occurred as a result of thermal stress in the Drift Scale Test, as measured in multiple-point borehole extensometers (BSC 2004 [DIRS 169864], Figure 7.4.2-2). The simulations of the displacement response in the Drift Scale Test, based on elastic thermal-hydrological-mechanical (THM) processes, were found to be in agreement with measurements. The dominant mode for stress-induced permeability change for THM processes was found to be elastic fracture opening or closing caused by changes in stress normal to the fractures, as opposed to changes in matrix permeability (BSC 2004

[DIRS 169864], Section 8.2). For seismically induced displacements and stresses, similar in amplitude to those found in the Drift Scale Test, the same conclusions apply to both the unsaturated zone and saturated zone. Therefore, based on the fault displacement hazard for the intact rock matrix, seismically related effects on rock-matrix hydrologic properties will be negligible and may be excluded on the basis of low consequence.

In summary, any changes to hydrologic processes as a result of changes to rock matrix properties caused by seismic activity are expected to be negligible. Based on the previous discussion, omission of FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) will not result in a significant adverse change in the size or timing of either radiological exposures to the RMEI or radionuclide releases to the accessible environment. Therefore, this FEP is excluded from the performance assessments conducted to demonstrate compliance with 10 CFR 63.311 and 63.321 and with 10 CFR 63.331 [DIRS 186479], on the basis of low consequence.

Seismic Activity Changes Porosity and Permeability of Faults

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*No modification to the parent report, except for the first paragraph of the un-numbered section "Evaluation of Changes in Fault Zone Hydrologic Properties in the UZ," which is replaced by the paragraphs below:*]

Evaluation of Changes in Fault Zone Hydrologic Properties in the UZ—The effects of a given fault displacement on unsaturated zone hydrologic properties could be evaluated using process-level calculations for the effects of the induced stress and strain on fracture geometry. However, this direct approach was not used to specifically evaluate seismic effects because of the large uncertainty in the specification of the seismic event and complexity of translating seismic motion along faults into imposed stresses. An alternative bounding approach that employed two sensitivity studies was used to assess the potential effects of fault displacement on changes in fracture apertures and consequently on fracture hydrologic properties (Appendix I).

Two bounding cases were considered. The first case considered changes in fracture aperture over the entire model domain (including faults). The range of aperture evaluated was selected to accommodate fault displacement hazard for the Solitario Canyon fault with a mean annual probability of exceedance of 10^{-8}. The second case, which considers change in fracture properties within the faults only, is directly applicable to this FEP. The results of the second sensitivity study have shown that fracture aperture changes confined to fault zones resulted in virtually no effect on transport behavior in the unsaturated zone (Appendix I, Section I3.3.1).

Changes in fault properties would also have little effect on flow above the repository because faults carry about 1% of the flow in this region of the unsaturated zone (SNL 2007 [DIRS 184614], Tables 6.6-1 and 6.6-2). Fault permeabilities are high relative to the predicted flux. Changes in fault properties, other than a very substantial reduction in fault permeability, would not be expected to affect this flow percentage. This is because the percentage of flow in the faults above the repository is related to the fault area at the ground surface available for direct infiltration into faults and lateral flow processes in the unsaturated zone. A substantial reduction in fault permeability would result in flow redirection into more permeable zones near faults and would not have a significant effect on water arrival at the repository. A similar conclusion can be reached concerning transient flow between the ground surface and the repository. Any change in transient flow would be limited to the small fraction of flow that moves through faults.

FEP NAME:

Seismic Activity Changes Porosity and Permeability of Fractures

FEP DESCRIPTION:

[*No modification to the parent report.*]

SCREENING DECISION:

[*No modification to the parent report.*]

SCREENING JUSTIFICATION:

[*No modification to the parent report, , except for the un-numbered sections "Potential for Fracture Reactivation or the Development of New Fractures" and "Evaluation of Changes in Fracture Hydrologic Properties in the Unsaturated Zone as a Result of Reactivation," which are replaced by the paragraphs below:*]

Potential for Fracture Reactivation or the Development of New Fractures—Redistribution of strain could open new fractures and close some existing fractures, as discussed by Gauthier et al. (1996 [DIRS 100447], p. 163). Much of this redistribution would be expected to occur within the fault zones. Although an analysis of fractures was not the primary purpose of the study, the PSHA (CRWMS M&O 1998 [DIRS 103731], p. 8-7) examines the probability of movement along existing fractures and the development of new fractures. The results lead to the conclusion that the development of new fractures, given current geologic conditions and the existing stress field, is not expected and would be of low consequence.

The PSHA (CRWMS M&O 1998 [DIRS 103731], Section 8.2.1, Points 7 and 8 in Table 8-1) examined displacement hazard for specific locations and conditions, including locations away from mapped faults that were characterized by hypothetical faults with small cumulative offset, shears, fractures, and intact rock. For each location and condition, the PSHA calculated exceedance probabilities for displacement values ranging from 0.1 cm to 500 cm. For intact rock and a mean annual probability of exceedance of 10^{-8}, the PSHA indicates that the displacement hazard is less than 0.1 cm (DTN: MO0401MWDRPSHA.000 [DIRS 185267], file: *s7d.frac_mean*; CRWMS M&O 1998 [DIRS 103731], p. 8-7, Point 7d in Table 8-1). This result is interpreted as the exceedance probability for creating new fractures or faults. Given the existing network of small to large fractures with varying apertures and other characteristics, and the low likelihood of developing new fractures due to seismic activity, the development of new fractures (displacement hazard less than 0.1 cm) in presently intact rock will not noticeably affect groundwater flow or radionuclide transport. Therefore, based on the PSHA, the development of new fractures due to seismic activity is inconsequential, particularly given the existing extensive fracture network.

For existing fractures within the repository area having no measured displacement, the PSHA indicates the displacement hazard with a mean annual probability of exceedance of 10^{-8} is less

than 1 cm (DTN: MO0401MWDRPSHA.000 [DIRS 185267], files: *s7c.frac_mean* and *s8c.frac_mean*; CRWMS M&O 1998 [DIRS 103731], Figures 8-10 and 8-13 for points 7c and 8c). Comparing mean annual exceedance probabilities for a 0.1 cm displacement for a site with intact rock to a site characterized by an existing fracture indicates that movement along existing fractures is more than 10,000 times more likely than the development of new fractures.

The small displacement hazard for intact rock, less than 0.1 cm for a mean annual-exceedance probability of 10^{-8}, corresponds to the level of displacement that occurred as a result of thermal stress in the Drift Scale Test, as measured in multiple-point borehole extensometers (BSC 2004 [DIRS 169864], Figure 7.4.2-2). The simulations of the displacement response in the Drift Scale Test, based on elastic THM processes, were found to be in agreement with measurements. The dominant mode for stress-induced permeability change for THM processes was found to be elastic fracture opening or closing caused by changes in stress normal to the fractures, as opposed to changes in matrix permeability (BSC 2004 [DIRS 169864], Section 8.2). For similar displacements and stresses (as found in the DST) associated with seismic motion, the same conclusions apply to both the unsaturated zone and saturated zone. Therefore, the small seismic displacements in the intact rock matrix will have a negligible effect on rock-matrix hydrologic properties and may be excluded on the basis of low consequence.

Field observations also suggest that creation of new fractures is not currently a dominant process at Yucca Mountain. Field observations indicate that the rock at Yucca Mountain is highly fractured (BSC 2004 [DIRS 166107], Section 6.1.4.1) and that some existing fractures and joints have been subject to reactivation. Evidence for reactivation of joints includes the presence of thin brecciated zones along some cooling joints and observable slip lineations along some joint surfaces (Sweetkind et al. 1996 [DIRS 106957]). Cooling joints, formed originally as tensional openings, have only normal displacement, not shear. However, thin selvages of tectonic breccia are locally present along the trace of some cooling joints, indicating later slip. Formation of brecciated/gouge zones is discussed in excluded FEPs 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) and 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults). Based on these field observations, the fracture and fault network appears to act as a significant preexisting weakness in the rock mass that can accommodate extensional strain through distributed slip along some reactivated joints and faults. Coupled with the results of the PSHA for displacement of intact rock, the field observations lead to an expectation that seismically related changes in strain are to be accommodated through reactivation of existing some fractures and faults, rather than through the initiation of new fractures.

Evaluation of Changes in Fracture Hydrologic Properties in the Unsaturated Zone as a Result of Reactivation—The reactivation of fractures can result in a change in fracture properties. The effects of changes in fracture system properties due to seismic activity on mountain-scale flow and radionuclide transport in the unsaturated zone have been investigated using a sensitivity approach (Appendix I). Changes in fracture hydrologic properties were considered in terms of variation in fracture aperture induced by fault displacement. The effects of fracture aperture changes are examined because several fracture hydrologic properties (permeability, capillary pressure, and porosity) are functions of fracture aperture. The sensitivity study was performed (Appendix I) with the nominal UZ three-dimensional flow model using several approaches that together provided bounding cases for determining whether changes in fractures will significantly

impact repository performance. The analysis was performed using a dual-permeability active-fracture flow model and was based on fracture aperture changes that could result from changes in strain conditions or other factors. Given a change in fracture aperture, other fracture hydrologic properties (permeability, capillary pressure, and porosity) were estimated using theoretical models (Appendix I). Calculations were then performed for unsaturated flow and transport using the modified fracture properties and the results were compared to the corresponding base case (Section I3.3). The sensitivity study (Appendix I) included two bounding cases: (1) uniform change in fracture properties throughout the UZ flow model domain and (2) change in fracture properties within the faults only. The first bounding case is particularly applicable to this FEP; the latter case is directly applicable to and is discussed in excluded FEP 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults). The two bounding cases were chosen to bound a range of fracture-aperture changes resulting from fault movement. No direct observations for Yucca Mountain relate stress caused by fault displacement to strain and the resultant changes in fracture aperture (Appendix I).

A maximum ten-fold increase in fracture aperture was selected as the model upper-bound value. The justification for this treatment (Appendix I) cites distance-strain relationships derived from models for a 1-m displacement along a strike-slip fault at Yucca Mountain, and for a 1-m displacement on a theoretical normal fault. The changes in fracture apertures for the sensitivity analysis were derived presuming a 10-m fault movement along the Solitario Canyon fault and multiplying the strains cited in the justification for the 1-m faults. The 10-m displacement represents the 85th percentile value for displacement hazard on the Solitario Canyon fault with a 10^{-8} annual probability of exceedance (DTN: MO0401MWDRPSHA.000 [DIRS 185267], files: *s2.frac_mean*; CRWMS M&O 1998 [DIRS 103731], Figure 8-3). For the Solitario Canyon fault, there is a large uncertainty in the displacement hazard with a 10^{-8} annual probability of exceedance. Values range from a median of 3 m to a mean of about 13 m. By contrast, the maximum measured single-event Quaternary displacement on the Solitario Canyon fault over about the last 200,000 years is only 1.3 m (Ramelli et al. 1996 [DIRS 101106], Table 4.7.3). Therefore, the sensitivity analysis parameterization provides a reasonable assessment of potential changes in fracture aperture that could result from seismic activity at Yucca Mountain.

The results of geomechanical models used to investigate the amount of strain induced by fault movements in the rock at Yucca Mountain suggest that a change by a factor of 10 in fracture aperture would bound the effects of tensile strain from such a fault movement (Appendix I, Section I3.2.4). Based on the cubic law for fracture permeability, a change by a factor of 10 in aperture leads to a change by a factor of 1,000 in permeability. Fracture permeabilities reduced by a factor of 1,000 were found to be inconsistent with the infiltration rates imposed on the model, because the bulk permeability was insufficient to accommodate the flow conditions. So, either reduced infiltration rates or a smaller reduction factor for the aperture would need to be used. Because the reduced apertures lead to reduced transport rates, this sensitivity does not show a potential adverse impact on performance. Therefore, a case with a reduction in aperture of a factor of 0.2 is considered sufficient.

The results of the sensitivity study have shown that fracture aperture changes confined to fault zones resulted in virtually no effect on transport behavior in the unsaturated zone (Appendix I, Section I3.3.1) and that increased fracture aperture applied over the entire unsaturated zone

domain results in effects that are no more significant than other uncertainties related to infiltration that are included in the TSPA (Appendix I, Section I4).

This result is also supported by the parameter sensitivity study for unsaturated zone flow (BSC 2005 [DIRS 174116]) and corresponding effects on radionuclide transport (SNL 2008 [DIRS 184748], Section 6.6.3[b]). For this sensitivity, fracture permeability is varied by one standard deviation. The sensitivity was conducted for both an increase and decrease in permeability by this factor, with changes to fracture permeability occurring globally over the entire model domain (BSC 2005 [DIRS 174116], Tables 6.2-1 and 6.2-4). The resulting flow fields were analyzed for effects on radionuclide transport. The transport results show that global variations in fracture permeability have only a small effect on transport relative to other uncertainties (SNL 2008 [DIRS 184748], Section 6.6.3[b]). The effects of fracture permeability in these sensitivities are expected to be overestimated because the effects of changes in capillary strength, which are negatively correlated with permeability (SNL 2007 [DIRS 181244], Section 6.5.1.1), would tend to offset changes in permeability. This is because increased fracture permeability leads to greater flow in fractures, but the associated reduction in capillary strength (represented by an increase in the fracture α), leads to a reduction in fracture flow through enhanced matrix imbibition. This effect may be seen in the response to unsaturated zone flow distributions between fractures, matrix, and faults with changes in fracture α (BSC 2005 [DIRS 174116], Table 6.4-1 (c)) and by the effects of changes in fracture α on radionuclide transport (SNL 2008 [DIRS 184748], Figures 6-25[b] and 6-26[b]).

J10.1[a] QUALIFICATION OF DATA FROM NATIONAL RESEARCH COUNCIL 1992

Data Set for Qualification: The data from the National Research Council report (National Research Council 1992) to be qualified for intended use within this FEP concern the predicted changes in the water table elevation in response to seismic activity. The intended use of the data overlaps with FEPs 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) and 2.2.06.02.0A (Seismic Activity Changes Porosity and Permeability of Faults) and includes the following statements:

- Results from the regional stress model approach indicated a maximum water table rise of 50 m (National Research Council 1992 [DIRS 105162], Chapter 5, p. 116).

- Nonetheless, the isotopic evidence now available indicates that no prolonged excursion of the water table above its present level has occurred in the last ca. 100 ka (National Research Council 1992 [DIRS 105162], Chapter 6, p. 134)

Qualification Method: The same data obtained from the same reference and used in an analogous context were qualified for intended use in FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock). The data were qualified for intended use using the Technical Assessment method (SCI-PRO-001, Attachment 3, Method 5) with the consideration of the qualifications of personnel or organizations generating the data and the extent to which the data demonstrate the properties of interest. The rationale for selecting the technical assessment data qualification method and the attributes of the data qualification process used for FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) are also applicable to qualifying the data from the National Research Council report (National Research Council 1992 [DIRS 105162]) for the intended use in FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Data Qualified for Intended Use: Based on the evidence provided for FEP 2.2.06.01.0A (Seismic Activity Changes Porosity and Permeability of Rock) and the intended use of the data in FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity), the data from the National Research Council (1992 [DIRS 105162]) are appropriate and are qualified for intended use in the screening justification for FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

J10.2[a] QUALIFICATION OF DATA FROM BELCHER 2004

Data set for qualification:

Belcher, W.R. 2004. *Death Valley Regional Ground-Water Flow System, Nevada and California - Hydrogeologic Framework and Transient Ground-Water Flow Model*. Scientific Investigations Report 2004-5205. Reston, Virginia: U.S. Geological Survey. ACC: MOL.20050323.0070. [DIRS 173179].

Description of Use: In the vicinity of Yucca Mountain, the Death Valley Regional Groundwater Flow Model has estimated the specific storage of confined aquifers of between 10^{-7} and 10^{-4} m^{-1} and a specific yield of unconfined aquifers of about 0.2 (Belcher 2004 [DIRS 173179], Table F-14 and Figure F-38). Considering confined aquifer thicknesses of about 10^{2} m implies a storativity of between about 10^{-5} and 10^{-2}, a factor of 10^{4} to 10^{1} less than the specific yield of the unconfined aquifers. These data are used as typical examples to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Method of qualification: Data are qualified by the equivalent QA Program approach.

Evaluation Criteria: The Equivalent QA Program approach is used for the qualification of these data to show the acquisition, development, or processing of data can be demonstrated to be functionally equivalent (i.e., similar in scope and implementation) to the general process requirements of the QARD. The employed practices or procedures must demonstrate industry acceptable scientific, engineering, or administrative practices or processes with appropriate documentation.

Evaluation of the technical correctness of the data to be qualified: Observations of water level responses that are interpreted to result from earthquake-induced poroelastic deformation generally are from open boreholes where these water level responses reflect the change in pore pressure associated with the deformation. Earthquake-induced response groundwater level changes may be associated with changes in hydraulic head when the well is open to a confined aquifer(s) or to water table elevation changes when the well is open to an unconfined aquifer. The reason for the greater amplitude of response of the water level in confined aquifers is the result of the smaller storativity of confined aquifers. Considering a given poroelastic compression with the resultant volume of water released per unit surface area of the aquifer, the smaller storativity of the confined aquifer will result in a higher water level rise in boreholes that are open to the confined aquifer.

Evaluation results: All U.S. Geological Survey (USGS) scientific investigation reports have Bureau Approval (previously referred to as "Director's Approval"), which validates the scientific excellence of the information product. Bureau Approval ensures that all appropriate technical reviews have been conducted and that the product is consistent with all pertinent USGS and

departmental policies. This publication was thoroughly reviewed by technical experts outside the USGS as well.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Qualifications of Personnel or Organizations Generating the Data: Claudia Faunt, the first author of Chapter F, *Transient Numerical Model* in Belcher (2004 [DIRS 173179]), earned a Ph.D. in Geological Engineering from the Colorado School of Mines and is currently a hydrologist at the USGS in San Diego, California. She is an expert in the development of hydrogeologic models for groundwater model development using advanced three-dimensional database and visualization methods.

J10.3[a] QUALIFICATION OF DATA FROM BREDEHOEFT 1992

Data set for qualification:

Bredehoeft, J.D. 1992. "Response of the Ground-Water System at Yucca Mountain to an Earthquake." Appendix D of *Ground Water at Yucca Mountain: How High Can It Rise?* Washington, D.C.: National Academy Press. TIC: 233195. [DIRS 101122].

Description of Use: Bredehoeft (1992 [DIRS 101122]) presents a three-dimensional, dislocation model of earthquake-related water table rise used in the analyses to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity). A normal faulting earthquake with 1-m slip whose rupture was 30-km long and extended at a 60-degree dip to a depth of 10 km was used in the analysis. For this case, Bredehoeft (1992 [DIRS 101122]) found that the head change produced by the earthquake was quickly dissipated by local flow. The impact on the water table elevation was a rise on the order of 1 m.

Method of qualification: Data are qualified by corroboration with independent data and independent simulations of seismically induced water table rise.

Evaluation Criteria: Data are qualified by corroboration with independent data and independent simulations of seismically induced water table rise.

Evaluation of the technical correctness of the data to be qualified: The Panel on Coupled Hydrologic/Tectonic/Hydrothermal Systems at Yucca Mountain, Nevada established by the National Research Council considered two models of earthquake-related water table rise: a dislocation model and a regional stress change model (National Research Council 1992 [DIRS 105162], Chapter 5). Analyses using the dislocation model approach were carried out by Carrigan et al. (1991 [DIRS 100967]) and Bredehoeft (1992 [DIRS 101122]). For typical Basin and Range earthquakes (normal faulting with 1-m slip), Carrigan et al. (1991 [DIRS 100967]) used a two-dimensional model and found the increase in water table elevation was 2 to 3 m for different combinations of elastic properties and aquifer thickness. Extrapolating their results to larger slip values, they found that for a 4-m slip earthquake a water table rise of 17 m was predicted. For a fault-patch model that produced greater strains and stresses, water table rise ranged from 6 to 12 m for different permeability assumptions. Bredehoeft (1992 [DIRS 101122]) used a three-dimensional model to analyze a normal faulting earthquake with 1

m slip whose rupture was 30-km long and extended at a 60-degree dip to a depth of 10 km. For this case, he found that the head change produced by the earthquake was quickly dissipated by local flow. The impact on the water table elevation was a rise on the order of 1 m.

Evaluation results: These simulated water-table rises are qualified by corroboration with observations cited by Carrigan et al. (1991 [DIRS 100967]). The Dixie Valley – Fairview Peak, Nevada, earthquake, magnitude approximately 7, produced water table excursions of 1 to 3 m, as well as long-term changes in the regional hydrology (Raney 1988 [DIRS 147173], p. 44). The 1983 Borah Peak, Idaho earthquake, magnitude approximately 7.3, caused increases of about 4 m, with water levels returning to normal within two weeks to two months (Dudley 1990 [DIRS 147175]).

Gauthier et al. (1996 [DIRS 100447], pp. 163 to 164) expanded on the work of Carrigan et al. (1991 [DIRS 100967]) and Bredehoeft (1992 [DIRS 101122]) using the dislocation model. For the flow part of the problem, they used a dual-permeability formulation involving both fracture and matrix flow. They considered three different fault types: normal, listric, and strike-slip. For all three fault types, an earthquake with a 1-m displacement and 30-km rupture length was modeled. For the normal and strike-slip cases, the vertical extent of faulting was 10 km; for the listric case the vertical extent of faulting was 2 km. The greatest response was found for the strike-slip case in which complete saturation of fractures occurs within 1 hour to an elevation of 50 m above the steady-state water table, but drops to 10% saturation after 20 hours. Matrix saturations change little. Smaller rises were obtained for the normal- and listric-faulting cases. The simulated system returned to steady-state conditions within six months.

These data serve to qualify the simulation results.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Carrigan et al. (1991 [DIRS 100967]), Dudley (1990 [DIRS 147175]), Gauthier et al. (1996 [DIRS 100447]), Raney (1988 [DIRS 147173]).

Qualifications of Personnel or Organizations Generating the Data: John D. Bredehoeft earned a BSE degree in Geological Engineering with honors from Princeton University, and MS and PhD degrees in Geology with a minor in Civil Engineering – Soil Mechanics from The University of Illinois. He worked at the U.S. Geological Survey for 32 years. At the USGS he engaged in both research and high-level management. He is the author of more than 100 research papers in the refereed scientific literature. While at the USGS, Bredehoeft testified before Congress on such diverse topics as the USGS study of the Potomac Estuary, National Policy on the geologic disposal of nuclear wastes, water in the western United States, and the use of numerical models in management decisions. He was a member of the National Academy of Sciences/National Research Council (NAS/NRC) Committee on the Waste Isolation Pilot Plant (WIPP), and a member of the NAS/NRC Panel that reviewed groundwater concerns for the Yucca Mountain Nuclear Repository. He received numerous awards: member of the U.S. National Academy of Engineering; Editor of the scientific journal, Ground Water (1991-95); received both the Horton Medal of the American Geophysical Union (the highest award given to

a hydrologist), the Penrose Medal of the Geological Society of America (the highest award given to a geologist), and made a life-member of the National Ground Water Association (their highest award).

J10.4[a] QUALIFICATION OF DATA FROM CARRIGAN ET AL. 1991

Data set for qualification:

Carrigan, C.R.; King, G.C.P.; Barr, G.E.; and Bixler, N.E. 1991. "Potential for Water Table Excursions Induced by Seismic Events at Yucca Mountain, Nevada." *Geology*, 19, (12), 1157-1160. Boulder, Colorado: Geological Society of America. TIC: 242407 [DIRS 100967].

Description of Use: Numerical simulations by Carrigan et al. (1991 [DIRS 100967]) of tectonohydrological coupling involving earthquakes typical of the Basin and Range Province (approximately 1 m slip) produced 2 to 3 m excursions of a water table 500 m below the ground surface. Extrapolation to an event of about 4 m slip would result in a transient rise of 17 m near the fault (Carrigan et al. 1991 [DIRS 100967], p. 1,159). These data are used as typical examples to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Method of qualification: Data are qualified by corroboration with independent data and independent simulations of seismically induced water table rise. No planned method of qualification was abandoned.

Evaluation Criteria: The evaluation criteria, as stated in the data qualification plan (BSC 2004 [DIRS 174776]), are that none of the corroborating data or simulations indicate a water table rise greater than 12 m.

Evaluation of the technical correctness of the data to be qualified: Changes in water level due to seismic activity are identified in the FEP description as being possibly of consequence. Numerical simulations by Carrigan et al. (1991 [DIRS 100967]) of tectonohydrological coupling involving earthquakes typical of the Basin and Range Province (approximately 1 m slip) produced 2 to 3 m excursions of a water table 500 m below the ground surface. Extrapolation to an event of about 4 m slip would result in a transient rise of 17 m near the fault (Carrigan et al. 1991 [DIRS 100967], p. 1,159). Carrigan et al. (1991 [DIRS 100967]) modeled a 100 m wide fracture zone centered on a vertical fault, with vertical permeability increased by a factor of 10^3. Water level excursions in the fracture zone were twice as great as in the adjacent block. For a fault-fracture zone with 1 m slip, transient excursions of about 12 m can occur.

Evaluation results: These simulated water-table rises are qualified by corroboration with observations cited by Carrigan et al. (1991 [DIRS 100967]). The Dixie Valley – Fairview Peak, Nevada, earthquake, magnitude approximately 7, produced water table excursions of 1 to 3 m, as well as long-term changes in the regional hydrology (Raney 1988 [DIRS 147173], p. 44). The 1983 Borah Peak, Idaho earthquake, magnitude approximately 7.3, caused increases of about 4 m, with water levels returning to normal within two weeks to two months (Dudley 1990 [DIRS 147175]). These data serve to qualify the simulation results.

An independent model by Bredehoeft (1992 [DIRS 101122]) calculated a 1-m water table rise due to a magnitude 6 earthquake; this is consistent with the data cited above and the results of Carrigan et al. (1991 [DIRS 100967]).

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Raney (1988 [DIRS 147173], p. 44); Dudley (1990 [DIRS 147175]), Bredehoeft (1992 [DIRS 101122]).

Reference to data qualification plan: *Data Qualification Plan, Qualification of Water Table Rise Due to Seismic Activity, as Simulated by Carrigan et al. (1991 [DIRS 100967])* BSC 2004 [DIRS 174776].

J10.5[a] QUALIFICATION OF DATA FROM CHIOU ET AL. 2008

Data set for qualification:

Chiou, B.; Darragh, R.; Gregor, N.; and Silva, W. 2008. "NGA Project Strong-Motion Database." *Earthquake Spectra*, 24, (1), 23-44. Oakland, California: Earthquake Engineering Research Institute. TIC: 260403. [DIRS 186319].

Description of Use: For the observed distribution of earthquake stress parameters, a lognormal distribution with a median value of 30 bars and a lognormal standard deviation of 0.6 is used. The median value of 30 bars for point-source stress parameter is consistent with a static stress drop of about 30 bars that, for a circular fault rupture, is implied by the moment magnitude-rupture area relations of Wells and Coppersmith (1994 [DIRS 107201], Table 2A). Taking static stress drop as lognormally distributed, a median value of about 30 bars for static stress drop is also obtained using the database of earthquake information developed for the Next Generation of Ground-Motion Attenuation Models (NGA) project (public version 7.3, 02-14-06, http://peer.berkeley.edu/nga/flatfile.html) (Chiou et al. 2008 [DIRS 186319]).

Method of qualification: The method used is technical assessment.

Evaluation Criteria: The PEER NGA database is an update and extension to the PEER Strong Motion Database, first published in 1999. The latest PEER Strong Motion Database brings together over 10,000 strong ground motion records from 173 different earthquakes in a web-accessible format. The NGA database includes a larger set of records, more extensive meta-data, and some corrections to information in the original database.

Evaluation of the technical correctness of the data to be qualified: The "Next Generation of Ground-Motion Attenuation Models" (NGA) project is a multidisciplinary research program coordinated by the Lifelines Program of the Pacific Earthquake Engineering Research Center (PEER), in partnership with the U.S. Geological Survey and the Southern California Earthquake Center.

The objective of the project is to develop new ground-motion prediction relations through a comprehensive and highly interactive research program. Five sets of ground-motion attenuation

models were developed by teams working independently but interacting with one another throughout the development process. The main technical issues being addressed by the NGA teams include magnitude scaling at close-in distances, directivity effects, polarization of near-field motion (fault-strike-normal component vs. fault-strike-parallel component), nonlinear amplification by shallow soil, and sedimentary basin amplification. The attenuation relationships development is also facilitated by the development of an updated and expanded database of recorded ground motions; conduct of supporting research projects to provide constraints on the selected functional forms of the attenuation relationships; and a program of interactions throughout the development process to provide input and reviews from both the scientific research community and the engineering user community.

Evaluation results: Confidence in the empirical correlations developed in this database is therefore warranted, and the data are qualified for the purpose of screening FEP 1.2.10.01.0A.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

J10.6[a] QUALIFICATION OF DATA FROM GRECKSCH ET AL. 1999

Data set for qualification:

Grecksch, G.; Roth, F.; and Kumpel, H.-J. 1999. "Coseismic Well-Level Changes Due to the 1992 Roermond Earthquake Compared to Static Deformation of Half-Space Solutions." *Geophysical Journal International*, 138, 470-478. [Oxford, England: Wiley-Blackwell]. TIC: 260449. [DIRS 186477].

Description of Use: A review of literature since 1992 indicates that dislocation model predictions of strain caused by fault displacement during earthquakes can reasonably explain observations of zones of bulk rock compression and dilation. In addition, this same research indicates that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected given the poroelastic theory, although exceptions to this observation are known and reflect the many competing factors that affect the direction of water level change at any particular well in an area. One of the representative cases from literature is Grecksch et al. (1999 [DIRS 186477]), which is briefly described below. This paper is cited in the discussion to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Similarly, in an analysis of water level responses following an earthquake at Roermond, Netherlands, it was observed that the water-level response was in general agreement with the expected poroelastic response to volume strains (compression or dilation) predicted by a dislocation model of the event, with 16 of 19 wells with rising water levels corresponding to areas of compression and 7 of 9 wells with water level drops corresponding to areas of dilation, although the magnitudes and durations were larger than expected (Grecksch et al. 1999 [DIRS 186477]).

Method of qualification: The method used is technical assessment.

Evaluation Criteria: The methodology is acceptable. The methodology is comparison between measured water level changes in 81wells that penetrate unconfined or poorly confined aquifers, and calculated surface static volume strain.

Evaluation of the technical correctness of the data to be qualified: Although there are no direct corroborating data for this specific earthquake, the theory advanced by this paper, that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected from poroelastic theory, is also supported by other inputs qualified in this appendix (Jonsson et al. 2003 [DIRS 186291], Quilty and Roeloffs 1997 [DIRS 186478]), Sato et al. 2004 [DIRS 186293]). Therefore these publications corroborate each other.

Evaluation results: Confidence in the data for the purposes of supporting the poroelastic model of co-seismic water level changes is therefore warranted.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Jonsson et al. (2003 [DIRS 186291]), Quilty and Roeloffs (1997 [DIRS 186478]), Sato et al. (2004 [DIRS 186293]).

Qualifications of Personnel or Organizations Generating the Data: The qualifications of personnel and organizations generating the data are comparable to the qualification requirements for generating similar data in support of the Yucca Mountain license application: This paper summarizes the Ph.D. dissertation of Gunnar Grecksch at the University of Bonn. It was peer reviewed before publication; Geophysical Journal International is published for the Royal Astronomical Society.

J10.7[a] QUALIFICATION OF DATA FROM JONSSON ET AL. 2003

Data set for qualification:

Jonsson, S.; Segall, P.; Pedersen, R.; and Bjornsson, G. 2003. "Post-Earthquake Ground Movements Correlated to Pore-Pressure Transients." *Nature*, 424. London, England: Nature Publishing Group. TIC: 260376. [DIRS 186291].

Description of Use: A review of literature since 1992 indicates that dislocation model predictions of strain caused by fault displacement during earthquakes can reasonably explain observations of zones of bulk rock compression and dilation. In addition, this same research indicates that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected given the poroelastic theory, although exceptions to this observation are known and reflect the many competing factors that affect the direction of water level change at any particular well in an area. One of the representative cases from literature is Jonsson et al (2003 [DIRS 186291]), which is briefly described below. This paper is cited in the discussion to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Earthquakes in June 2000 along two right-lateral strike-slip faults in southern Iceland exhibit coseismic deformation consistent with a dislocation model, with upward ground movement associated with coseismic extension zones northeast and southwest of the fault and downward ground movement associated with coseismic compression zones northwest and southeast of the fault (Jonsson et al 2003 [DIRS 186291], Figure 2). In addition, predicted coseismic pore-pressure response was shown to reasonably reproduce the observed water level changes in nearby geothermal wells, with areas of water level rise being associated with zones of compression and water level decline being associated with zones of dilation (Jonsson et al. 2003 [DIRS 186291], Figure 3).

Method of qualification: The method used is technical assessment.

Evaluation Criteria: The methodology is acceptable. The methodology is development of a correlation between measured water level changes and ground motion, developed by the combination of satellite radar interferograms and water-level changes in geothermal wells following two magnitude-6.5 earthquakes in the south Iceland seismic zone. The deformation is consistent with rebound of a porous elastic material in the first 1–2 months following the earthquakes. This interpretation is confirmed by direct measurements which show rapid (1–2-month) recovery of the earthquake-induced water-level changes. The data collected from these measurements are therefore appropriate for testing the hypothesis that changes in groundwater levels in wells that tap confined aquifers should be approximately proportional to volumetric strain.

Evaluation of the technical correctness of the data to be qualified: Although there are no direct corroborating data for this specific earthquake, the theory advanced by this paper, that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected from poroelastic theory, is also supported by Grecksch et al. (1999 [DIRS 186477]), Sato et al. (2004 [DIRS 186293]) and Quilty and Roeloffs (1997 [DIRS 186478]). Therefore these publications corroborate each other.

Evaluation results: Confidence in the data for the purposes of supporting the poroelastic model of co-seismic water level changes is therefore warranted.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Grecksch et al. (1999 [DIRS 186477]), Sato et al. (2004 [DIRS 186293]), Quilty and Roeloffs (1997 [DIRS 186478]).

Qualifications of Personnel or Organizations Generating the Data: The qualifications of personnel and organizations generating the data are comparable to the qualification requirements for generating similar data in support of the Yucca Mountain license application: Sigurjón Jónsson received a Ph.D. in 2002 from the Stanford University, Department of Geophysics, was a post-doctoral fellow at Harvard University during this work, and now is a senior researcher at ETH Zurich. Paul Segall received a Ph.D. in Geology from Stanford University and is now a professor in the department of Geophysics at Stanford.

J10.8[a] QUALIFICATION OF DATA FROM MANGA AND WANG 2007

Data set for qualification:

Manga, M. and Wang, C.-Y. 2007. *Earthquake Hydrology*. Treatise on Geophysics. Volume 4. 293-320. New York, New York: Elsevier. TIC: 260373. [DIRS 186289].

Description of Use: Earthquake-induced Response of Groundwater Level in Wells versus Response of Water Table Elevation. Observed water level responses discussed are generally for confined aquifers. Although researchers have not focused on water level responses in comparison to water table responses, the available information supports the conclusion that water table responses are generally much less (in several cases an order of magnitude less) than water level responses.

Coseismic water level responses in wells completed in confined aquifers following the 1999 M 7.5 Chi-Chi earthquake in Taiwan were observed to range from less than 1 m to more than 5 m, while water level changes in the uppermost unconfined aquifer were shown to be much smaller (ranging from 0 to 0.5 m) (Manga and Wang 2007 [DIRS 186289], p. 302).

Method of qualification: The method used is corroboration with independent data and independent observations.

Evaluation Criteria: The methodology is acceptable. Data are qualified by corroboration with independent data and independent observations of earthquake-induced response of groundwater level compared to the response of water table elevations.

Evaluation of the technical correctness of the data to be qualified: Manga and Wang (2007 [DIRS 186289]) describe the processes by which fluid pressure and hydrologic properties can change following an earthquake. Observations of water level responses that are interpreted to result from earthquake-induced poroelastic deformation generally are from open boreholes where these water level responses reflect the change in pore pressure associated with the deformation. Groundwater level changes may be associated with changes in hydraulic head when the well is open to a confined aquifer(s) or to water table elevation changes when the well is open to an unconfined aquifer. When wells are open to multiple aquifers, the water level in the well will be controlled by the hydraulic head in the most transmissive unit(s) intersecting the well.

Most of the observed water level changes in wells completed in confined aquifers following the 2003 Tokachi-oki M 8.0 earthquake in Japan could be explained by the poroelastic response and volumetric strain derived from a fault dislocation model, while an earlier earthquake in the same area had responses that could not be explained by poroelastic response because it included responses of unconfined aquifers, which are not highly sensitive to volumetric strain changes (Koizumi et al. 2005 [DIRS 186295]).

The reason for the greater amplitude of response of the water level in confined aquifers is the result of the smaller storativity of confined aquifers. Considering a given poroelastic compression with the resultant volume of water released per unit surface area of the aquifer, the smaller storativity of the confined aquifer will result in a higher water level rise in boreholes that are open to the confined aquifer. In the vicinity of Yucca Mountain, the Death Valley Regional

Groundwater Flow Model has estimated the specific storage of confined aquifers of between 10^{-7} and 10^{-4} m^{-1} and a specific yield of unconfined aquifers of about 0.1 (Belcher 2004 [DIRS 173179], Figure F-38). Considering confined aquifer thicknesses of about 10^{2} m implies a storativity of between about 10^{-5} and 10^{-2}, a factor of 10^{4} to 10^{1} less than the specific yield of the unconfined aquifers. Therefore, an earthquake capable of causing a water level rise of 10 m in the confined aquifers at Yucca Mountain would be expected to cause only a 1.0 to 0.001 m rise in the water table.

Evaluation results: Confidence in the data and observations for the purposes of supporting the earthquake-induced response of water level responses in comparison to water table responses is therefore warranted.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Belcher (2004 [DIRS 173179]), Koizumi et al. (2005 [DIRS 186295]).

Qualifications of Personnel or Organizations Generating the Data: Michael Manga is a professor of Earth and Planetary Science at the University of California, Berkeley where he has been on the faculty since 2001. His research interest is geological processes involving fluids, including problems in physical volcanology, geodynamics, hydrogeology, and geomorphology. He received a B.S. degree in geophysics from McGill University in 1990, a S.M. degree in Engineering Sciences in 1992 and a Ph.D. in Earth and Planetary Sciences in 1994 both from Harvard University. He was a Miller Fellow at the University of California, Berkeley from 1994 to 1996 and an assistance professor at the University of Oregon from 1996 to 2001.

Chi-Yuen Wang is a faculty member of the Earth and Planetary Science department at the University of California, Berkeley. He has been a professor since 1982 and taught at the university since 1967. His research interests are the interaction of water with earthquakes and active tectonics. He received his B.S. degree in Geology from Taiwan National University in 1954 and his Ph.D. in Geological Sciences from Harvard University in 1964. From 1964 to 1967 he was a geophysicist at the Smithsonian Astrophysical Observatory.

J10.9[a] QUALIFICATION OF DATA FROM QUILTY AND ROELOFFS 1997

Data set for qualification:

Quilty, E.G. and Roeloffs, E.A. 1997. "Water-Level Changes in Response to the 20 December 1994 Earthquake near Parkfield, California." *Bulletin of the Seismological Society of America*, 87, (2), 310-317. El Cerrito, California: Seismological Society of America. TIC: 260450. [DIRS 186478].

Description of Use: A review of literature since 1992 indicates that dislocation model predictions of strain caused by fault displacement during earthquakes can reasonably explain observations of zones of bulk rock compression and dilation. In addition, this same research indicates that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected given the poroelastic theory,

although exceptions to this observation are known and reflect the many competing factors that affect the direction of water level change at any particular well in an area. One of the representative cases from literature is Quilty and Roeloffs (1997 [DIRS 186478]), which is briefly described below. This paper is cited in the discussion to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Observations of step-like coseismic groundwater level changes in confined aquifers were also explained as the poroelastic response to static strains caused by the 1994 earthquake near Parkfield, California (Quilty and Roeloffs 1997 [DIRS 186478]). These authors concluded that the strains predicted by a dislocation model of the rupture were in good agreement with the changes in most of the wells.

Method of qualification: The method used is technical assessment.

Evaluation Criteria: The methodology is acceptable. The methodology is development of a correlation between measured water level changes and measured seismic strain. The Parkfield, California area is located on the San Andreas Fault about halfway between San Francisco and Los Angeles and has been intensively monitored with measurements of water level, creep, and borehole volumetric strain. The data collected from these measurements are therefore appropriate for testing the hypothesis that changes in groundwater levels in wells that tap confined aquifers should be approximately proportional to volumetric strain. Water level in eight wells was recorded by pressure transducers with a precision of about 1 mm, at intervals of 15 minutes or less, and were corrected for barometric pressure excursions and verified by manual observations.

Evaluation of the technical correctness of the data to be qualified: This paper has been peer reviewed prior to publication and has since been cited in 19 other peer-reviewed publications. The report was published in the *Bulletin of the Seismological Society of America*, which is the premier journal of advanced research in earthquake seismology and has been published continuously since 1911.

Although there are no direct corroborating data for this specific earthquake, the theory advanced by this paper, that that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected from poroelastic theory, is also supported by Grecksch et al. (1999 [DIRS 186477]), Jonsson et al. (2003 [DIRS 186291]), and Sato et al. (2004 [DIRS 186293]). Therefore these publications corroborate each other.

Evaluation results: Confidence in the data for the purposes of supporting the poroelastic model of co-seismic water level changes is therefore warranted.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Grecksch et al. (1999 [DIRS 186477]), Jonnson et al. (2003 [DIRS 186291]), Sato et al. (2004 [DIRS 186293]).

Qualifications of Personnel or Organizations Generating the Data: The qualifications of personnel and organizations generating the data are comparable to the qualification requirements

for generating similar data in support of the Yucca Mountain license application: Evelyn Roeloffs received a Ph.D. in 1982 from the University of Wisconsin, Department of Geology and Geophysics, and led the USGS Parkfield earthquake prediction experiment during 1990-1991.

J10.10[a] QUALIFICATION OF DATA FROM SATO ET AL. 2004

Data set for qualification:

Sato, T.; Matsumoto, N.; Kitagawa, Y.; Koizumi, N.; Takahashi, M.; Kuwahara, Y.; Ito, H.; Cho, A.; Satoh, T; and Tasaka, S. 2004. "Changes in Groundwater Level Associated with the 2003 Tokachi-Oki Earthquake." *Earth Planets and Space*, 56, 395-400. Tokyo, Japan: TERRA-PUB. TIC: 260410. [DIRS 186293]

Description of Use: A review of literature since 1992 indicates that dislocation model predictions of strain caused by fault displacement during earthquakes can reasonably explain observations of zones of bulk rock compression and dilation. In addition, this same research indicates that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected given the poroelastic theory, although exceptions to this observation are known and reflect the many competing factors that affect the direction of water level change at any particular well in an area. One of the representative cases from literature is Sato et al. (2004 [DIRS 186293]), which is briefly described below. This paper is cited in the discussion to exclude FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

A fault model of coseismic strain associated with fault displacement was shown to reasonably correlate to observed groundwater level changes associated with the 2003 Tokachi-oki earthquake. Water level changes in wells in areas of predicted dilation were observed to decrease, while water level changes in wells in areas of predicted contraction were observed to generally increase (Sato et al. 2004 [DIRS 186293], Figure 1).

Method of qualification: The method used is technical assessment.

Evaluation Criteria: The methodology is acceptable. The methodology is development of a correlation between measured water level changes and measured seismic strain. The data collected from 44 wells are therefore appropriate for testing the hypothesis that changes in groundwater levels in wells that tap confined aquifers should be approximately proportional to volumetric strain.

Evaluation of the technical correctness of the data to be qualified: This paper has been peer reviewed prior to publication. The report was published in the Earth Planets Space, which is published for the Seismological Society of Japan. Although there are no direct corroborating data for this specific earthquake, the theory advanced by this paper, that that water levels in wells within the zones of compression tend to rise while water levels in wells within zones of dilation tend to fall, as expected from poroelastic theory, is also supported by Grecksch et al. (1999 [DIRS 186477]), Jonsson et al. (2003 [DIRS 186291]), and Quilty and Roeloffs (1997 [DIRS 186478]). Therefore these publications corroborate each other.

Evaluation results: Confidence in the data for the purposes of supporting the poroelastic model of co-seismic water level changes is therefore warranted.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: Grecksch et al. (1999 [DIRS 186477]), Jonsson et al. (2003 [DIRS 186291]), Quilty and Roeloffs (1997 [DIRS 186478]).

J10.11[a] QUALIFICATION OF DATA FROM STOCK ET AL. 1985 AND STOCK AND HEALY 1988

Data sets for qualification:

Stock, J.M. and Healy, J.H. 1988. "Stress Field at Yucca Mountain, Nevada." Chapter 6 of *Geologic and Hydrologic Investigations of a Potential Nuclear Waste Disposal Site at Yucca Mountain, Southern Nevada*. Carr, M.D. and Yount, J.C., eds. Bulletin 1790. Denver, Colorado: U.S. Geological Survey. TIC: 203085 [DIRS 101022].

Stock, J.M.; Healy, J.H.; Hickman, S.H.; and Zoback, M.D. 1985. "Hydraulic Fracturing Stress Measurements at Yucca Mountain, Nevada, and Relationship to the Regional Stress Field." *Journal of Geophysical Research, 90*, (B10), 8691-8706. Washington, D.C.: American Geophysical Union. TIC: 219009 [DIRS 101027].

Description of Use: Stock and Healy (1988 [DIRS 101022]) measured in-situ stresses in four boreholes (USW G-1, USW G-2, USW G-3, and UE-25 p#1) and found that in all four boreholes $S_v > S_H > S_h$, where subscripts v, H, and h represent the vertical, greatest horizontal, and least horizontal stress, respectively. This corresponds to a normal faulting regime. The direction of least horizontal stress was N 60° W to N 65° W. Stock et al. (1985 [DIRS 101027]) report the same data. These data are used in FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity) to show that USW G-2, north of the repository, is in the same normal-faulting regime as the other boreholes.

Method of qualification: Data are qualified by corroboration with qualified data. No planned method of qualification was abandoned.

Evaluation Criteria: The evaluation criteria, as stated in the data qualification plan (BSC 2004 [DIRS 174775]), are that the corroborating data set confirm the relationship $S_v > S_H > S_h$ and that the direction of least horizontal stress reported in the data to be qualified agree within 30° of the direction reported in the corroborating data.

Evaluation of the technical correctness of the data to be qualified: In-situ stresses were measured by the hydraulic fracturing method. This method directly measures S_h by measuring the pressure of injected water needed to open a fracture, and observes the direction of S_h by acoustic televiewer logging. These are standard methods for measuring S_h. The data are therefore judged to be technically correct.

Evaluation results: These data are qualified by comparison with DTN: SNF37100195002.001 [DIRS 131356], which reports the mean of five hydraulic fracturing in situ stress measurements in a 30 m borehole drilled from the thermal test facility alcove in the ESF. The values reported there also show $S_v > S_H > S_h$, with S_h acting in N 75° W (±14°). DTN: SNF37100195002.001 [DIRS 131356] is qualified, and the values reported therein agree with those reported in Stock and Healy (1988 [DIRS 101022]) and Stock et al. (1985 [DIRS 101027]). Therefore both evaluation criteria specified in the qualification plan have been satisfied and the data of Stock and Healy (1988 [DIRS 101022]) and Stock et al. (1985 [DIRS 101027]) are qualified by corroboration.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Supporting information used in the qualification: DTN: SNF37100195002.001 [DIRS 131356]

Reference to data qualification plan:

Data Qualification Plan, Qualification of Stress Field at Yucca Mountain as Reported by Stock and Healy 1988 [DIRS 101022] and Stock et al. 1985 [DIRS 101027] (BSC 2004 [DIRS 174775]).

Qualifications of Personnel or Organizations Generating the Data: Joann M. Stock is Professor of Geology and Geophysics at California Institute of Technology. Her research interests involve a wide range of tectonic problems, including global and regional plate tectonic questions, including Tectonic Evolution of the Gulf of California and Stress Field variations around the Los Angeles region. She holds B.S., M.S., and Ph.D. from Massachusetts Institute of Technology.

J10.13[a] QUALIFICATION OF DATA FROM WELLS AND COPPERSMITH 1994

Data set for qualification:

Wells, D.L. and Coppersmith, K.J. 1994. "New Empirical Relationships Among Magnitude, Rupture Length, Rupture Width, Rupture Area, and Surface Displacement." *Bulletin of the Seismological Society of America*, 84, (4), 974-1002. El Cerrito, California: Seismological Society of America. TIC: 226273. [DIRS 107201].

Description of Use: For the observed distribution of earthquake stress parameters, a lognormal distribution with a median value of 30 bars and a lognormal standard deviation of 0.6 is used. The median value of 30 bars for point-source stress parameter is consistent with a static stress drop of about 30 bars that, for a circular fault rupture, is implied by the moment magnitude-rupture area relations of Wells and Coppersmith (1994 [DIRS 107201], Table 2A).

The vertical extent of rupture is computed using trigonometry and an empirical relation between the logarithm of rupture width and moment magnitude (Wells and Coppersmith 1994 [DIRS 107201], Table 2A). The probabilistic fault displacement hazard analysis assessed displacement hazard at the surface whereas the displacement value used in seismic moment

calculations is the average displacement over the entire fault rupture. Wells and Coppersmith (1994 [DIRS 107201], Figures 6 and 7) examined the relation between average surface displacement and average subsurface displacement. They estimated average subsurface displacement from seismic moment and assessments of earthquake rupture area. Based on data from 32 earthquakes, for the ratio of average surface displacement to average subsurface displacement, they found a range of 0.25 to 6.0 with a mode of 1.32.

Method of qualification: The method used is technical assessment.

Evaluation Criteria: The methodology is acceptable. Source parameters for 421 historical earthquakes worldwide were critically evaluated and compiled to develop a series of empirical relationships among moment magnitude (M), surface rupture length, subsurface rupture length, downdip rupture width, rupture area, and maximum and average displacement per event.

Evaluation of the technical correctness of the data to be qualified: This paper was peer reviewed prior to publication and has since been cited in over 1000 other publications. The report was published in *Bulletin of the Seismological Society of America*, which is the premier journal of advanced research in earthquake seismology and has been published continuously since 1911. The completeness of the database used to develop these relationships, and the extensive citation of this article make it, in effect, a source of accepted data.

Evaluation results: Confidence in the empirical correlations developed in this paper is therefore warranted, and the data are qualified for the purpose of screening FEP 1.2.10.01.0A.

Limitations on the use of the data: This qualification is limited to use in this report, as described above.

Qualifications of Personnel or Organizations Generating the Data: The qualifications of personnel generating the data are comparable to the qualifications of personnel developing similar data for the YMP License Application process: Donald Wells received the M.S. degree from San Diego State University, Department of Geology, in 1987, and has managed and participated in several studies to evaluate geologic and seismologic hazards around the world. Kevin Coppersmith convened the expert elicitation panel for *Probabilistic Volcanic Hazard Analysis Update (PVHA-U) for Yucca Mountain, Nevada* (SNL 2008 [DIRS 185746]); he received a Ph.D. from the University of California at Santa Cruz, Department of Earth Sciences, in 1979.

APPENDIX K[a]
IMPLICATIONS OF THE YUCCA MOUNTAIN PROBABILISTIC SEISMIC HAZARD ANALYSIS FOR EARTHQUAKE-INDUCED WATER TABLE RISE

K1[a]. INTRODUCTION

A key issue in screening FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity), is the potential at Yucca Mountain for earthquake-induced water table rise. A Panel established by the National Academy of Sciences' National Research Council "assessed the likelihood that the ground water level could rise to the height of the repository by *any* plausible geological process" during the 10,000 years following its closure (National Research Council 1992 [DIRS 105162], pp. 2 to 3). The Panel concluded that "only a modest rise in water table of less than 50 m is likely to occur as the result of a nearby earthquake" (National Research Council 1992 [DIRS 105162], p. 116). This conclusion was based on consideration of earthquake-related hydrologic responses observed worldwide, predictions of the poroelastic response of the earth's crust to earthquake-related strains made using dislocation and regional stress change models, and the likelihood of earthquakes occurring in the vicinity of Yucca Mountain.

In considering model predictions of earthquake-induced water table rise, the Panel focused on the regional stress change model because it yielded higher values of water table rise. The Panel carried out analyses using a model similar to the one developed by Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]). The Kemeny and Cook approach reduces the coupled thermo-hydro-mechanical problem to a simple mechanical model through the use of conservative assumptions. The result is a model that "should represent an upper bound on the rise in the water table due to an earthquake of a specified size" (Kemeny and Cook 1990 [DIRS 129658], p. 5-14). In the regional stress change model, the change in shear stress across the fault during an earthquake (static stress drop) leads to a compressive volumetric strain in the affected rock volume that reduces pore space. The reduced pore space causes water residing in the pores to be expelled and migrate vertically. The expelled water fills unsaturated pore space just above the water table, thereby raising its elevation. Key assumptions are:

- The stress/strain change caused by an earthquake uniformly affects a cuboid of rock that is related to the length of the fault (L) and the vertical extent of faulting (h). The lateral extent of the affected rock volume is assumed to extend perpendicular to the fault strike in both directions for a distance equivalent to the vertical extent of faulting. Thus, the affected volume of rock (V) is given by:

$$V = L \times h \times 2h \qquad \text{(Eq. K1[a])}$$

  All pore water displaced from the affected volume of rock instantaneously moves vertically up the stratigraphic column and occupies unsaturated pore space just above the water table.

Based on these and other assumptions, the Kemeny and Cook model relates water table rise (Δw, meters) to static stress drop ($\Delta\sigma$, bars) and vertical extent of faulting (h, meters) (Kemeny and Cook 1992 [DIRS 100989], Equation 6-1):

$$\Delta w = (1.2 \times 10^{-5}) \cdot \Delta\sigma_{static} \cdot h \qquad \text{(Eq. K2[a])}$$

Subsequent to the Panel assessment, promulgation of specific regulations for a repository at Yucca Mountain (10 CFR 63 [DIRS 186479], 40 CFR 197 [DIRS 185836]) changed the postclosure performance objectives such that water table rise now must be considered past 10,000 years through the period of geologic stability. In addition, a probabilistic seismic hazard analysis (PSHA) was carried out for Yucca Mountain (CRWMS M&O 1998 [DIRS 103731]). As part of the PSHA, six teams of experts characterized seismic sources in the vicinity of Yucca Mountain in terms of their geometry, rate of activity as a function of moment magnitude, and uncertainties in those parameters. The teams also characterized the potential for fault displacement at the earth's surface.

In this appendix, implications of the PSHA for water table rise are evaluated using the bounding model of Kemeny and Cook. Two approaches are used. First, seismic source characterization data for maximum moment magnitude and fault rupture dimension are used to determine static stress drop and the vertical extent of faulting. Equation K2[a] is then used to calculate a bounding water table rise for the given seismic source characterization. These results do not take into account the probability that the given seismic source characterization represents the actual state of nature. For those seismic source characterizations that give large predicted values of water table rise, a second phase of this approach takes into account the likelihood of such an earthquake occurring.

Second, fault displacement hazard results from the PSHA are used to determine the fault displacement on a block-bounding fault that has a mean annual probability of exceedance of 10^{-8}. This fault displacement value is used along with fault rupture dimensions for block-bounding faults from the PSHA to determine static stress drop and vertical extent of faulting. As in the first approach, Equation K2[a] is then used to calculate bounding water table rise. The calculated values of water table rise represent those that are consistent with the maximum fault displacement hazard that is required to be considered in the total system performance assessment.

The results of these analyses provide information supporting the screening evaluation for FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity). They show that the exclusion screening decision is consistent with the results of the PSHA.

K2[a]. INPUTS

Direct input to the analysis described in this appendix consists of results from the PSHA for Yucca Mountain (CRWMS M&O 1998 [DIRS 103731], Data Tracking Number [DTN] MO0401MWDRPSHA.000 Revision 3 [DIRS 185267]). For one analysis approach, input data consist of interpretations of maximum moment magnitude, subsurface geometry (i.e., vertical extent of faulting and fault dip), fault length, recurrence rate, and logic tree branch probability. Maximum moment magnitude, subsurface geometry, recurrence rate, and branch probability are

taken directly from PSHA input files (DTN: MO0401MWDRPSHA.000 Revision 3 [DIRS 185267]). Fault length data are implicitly contained in input fault geometry files that list coordinates of points defining a given fault interpretation. However, the fault length values used in the calculations are taken from summaries prepared by the PSHA seismic source characterization expert teams (CRWMS M&O 1998 [DIRS 103731], Appendix E), in which fault length interpretations are provided in tabular form.

For a second analysis approach, fault geometry interpretations and fault displacement hazard results for a site on the Solitario Canyon fault form the input. The fault displacement hazard for a site on the Solitario Canyon fault is used because the Solitario Canyon fault is a typical block-bounding fault and has the highest fault displacement hazard of the sites evaluated.

K3[a]. ASSUMPTIONS

Two assumptions are used in carrying out the analyses described in this appendix.

K3.1[a] CIRCULAR FAULT RUPTURE

Assumption: The value of static stress drop determined from fault rupture geometry and maximum moment magnitude or displacement is adequately determined using a relation for a circular fault rupture.

Discussion: Determination of static stress drop from seismic moment and rupture dimension depends on the fault mechanism (e.g., strike-slip, dip-slip) and geometric rupture model (e.g., circular, rectangular) (Schramm and Stein 2009 [DIRS 186465], Table 1, Figure 3). For a fault rupture with a given seismic moment, if rupture area is held constant, static stress drop determined for a circular fault yields a value that is equal to or greater than the one determined assuming a strike-slip or dip-slip rectangular fault rupture, for rupture aspect ratios (length:width) up to 8.

Seismic source characterization carried out during the PSHA results in only a few cases in which the nominal aspect ratio is greater than 8. These cases represent linked or simultaneously rupturing faults for which the length of individual fault segments has been summed to determine the overall tabulated length. This approach is taken because length is used in some approaches to estimate maximum moment magnitude. However, the geometry of fault segments making up these sources generally is characterized by considerable overlap normal to the strike direction, rather than an end-to-end arrangement. Thus the aspect ratio of the source is actually smaller than inferred from the tabulated length.

Use of a circular fault rupture model with an area equal to that for a rectangular source, therefore provides an adequate basis for calculating static stress drops consistent with the PSHA seismic source characterization.

Confirmation Status: This assumption does not need to be confirmed.

K3.2[a] BOUNDING FAULT DISPLACEMENT

Assumption: The fault displacement hazard value for the Solitario Canyon fault with a mean annual probability of exceedance of 10^{-8} is an appropriate bounding value for use in assessing seismically related water table rise.

Discussion: For a circular fault, static stress drop ($\Delta\sigma$) is related to average displacement ($\overline{D}$) over the fault rupture area through the relation (Kanamori and Anderson 1975 [DIRS 182963], Figure 1):

$$\Delta\sigma = \frac{7\pi}{16}\mu\frac{\overline{D}}{a}$$

in which μ is shear modulus and a is fault radius. One approach to evaluate the potential for water table rise using the bounding model of Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989] is to use the results of the probabilistic fault displacement hazard analysis for Yucca Mountain. The value of fault displacement used in the evaluation is taken as the fault displacement hazard for the Solitario Canyon fault (CRWMS M&O 1998 [DIRS 103731], Site 2 in Figure 4-9) with a mean annual probability of exceedance of 10^{-8}. Linearly extrapolating the logarithms of displacement and mean annual probability of exceedance from the probabilistic fault displacement hazard analysis (DTN: MO0401MWDRPSHA.000 [DIRS 185267]), this value is determined to be 1,300 cm. This value includes contributions from both primary faulting on the Solitario Canyon fault and secondary faulting on the Solitario Canyon fault in response to primary faulting on other faults in the vicinity of the site.

The probabilistic fault displacement hazard analysis assessed displacement hazard at the surface whereas the displacement value used in seismic moment calculations is the average displacement over the entire fault rupture. Wells and Coppersmith (1994 [DIRS 107201], Figures 6 and 7) examined the relation between average surface displacement and average subsurface displacement. They estimated average subsurface displacement from seismic moment and assessments of earthquake rupture area. Based on data from 32 earthquakes, for the ratio of average surface displacement to average subsurface displacement, they found a range of 0.25 to 6.0 with a mode of 1.32.

Results of the probabilistic fault displacement hazard analysis for surface displacement are used without adjustment in the evaluation of seismically related water table rise. This approach is justified because:

- Fault surface displacement hazard includes contributions from both primary and secondary faulting, whereas for water table rise calculations an average subsurface displacement from primary faulting is needed. Surface displacement hazard gives somewhat larger values than would be obtained for primary faulting alone. At larger values of displacement, this effect is small.

- Estimates of average subsurface displacement are uncertain. In particular, assessment of the fault rupture area is not determined directly, but usually estimated from the distribution of aftershocks.

- The Kemeny and Cook model is developed to provide bounding values of seismically related water table rise and thus is conservative.

Confirmation Status: This assumption does not require confirmation.

K4[a]. ANALYSIS

As described in Section K1[a], Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]) related earthquake-induced water table rise to the static stress drop and vertical extent of faulting associated with an earthquake (Equation K2[a]). They used a regional stress change model to determine the earthquake-induced change in volumetric strain, and reduced the coupled hydro-thermal-mechanical response of a poroelastic medium to a simple mechanical model through the use of assumptions. By making assumptions that would tend to lead to greater water table rise, they provide a simple model that yields a bounding estimate.

Because the Kemeny and Cook model relates earthquake-induced water table rise to static stress drop and vertical extent of faulting, and results from the PSHA for Yucca Mountain can be used to calculate values for those parameters, bounding water table rise that is consistent with the PSHA characterization of fault sources can be determined. The results of such analyses can then be evaluated with respect to the screening discussion for FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity).

Two approaches are used to examine the implications of the Yucca Mountain PSHA with respect to earthquake-induced water table rise. One approach uses seismic source characterization data developed as part of the PSHA to calculate static stress drop. The static stress drop is then used along with the associated vertical extent of faulting to estimate earthquake-induced water table rise. Water table rise is calculated using the regional stress change model of Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]). The Kemeny and Cook implementation was developed as a bounding representation of the hydrologic response of the crust, modeled as a poroelastic medium, to an earthquake.

A second approach calculates static stress drop using fault displacement hazard determined in the PSHA for a site on the Solitario Canyon fault. As in the first approach, the calculated static stress drop is then used along with the associated vertical extent of faulting to estimate water table rise.

As part of the PSHA, one seismic source characterization expert team (SBK) developed a discrete probability distribution for static stress drop as part of their approach to estimating maximum magnitude (M_{max}) (CRWMS M&O 1998 [DIRS 103731], Appendix E, p. SBK-34). The distribution consisted of static stress drop values of 30, 35, 50, and 100 bars with respective weights of 0.2, 0.5, 0.25, and 0.05. Using the largest value from the static stress drop distribution (100 bars) and the largest value for the thickness of the seismogenic crust from the SBK characterization (17 km) (CRWMS M&O 1998 [DIRS 103731], Table 4-1) in Equation K2[a] gives a calculated bounding water table rise of 20 m.

K4.1[a] BOUNDING WATER TABLE RISE FROM SOURCE CHARACTERIZATION DATA DEVELOPED IN THE PROBABILISTIC SEISMIC HAZARD ANALYSIS

Kanamori and Anderson (1975 [DIRS 182963], Figure 1) summarize the relation between seismic moment and static stress drop and fault dimension. For a circular fault:

$$M_0 = \frac{16}{7}\,\Delta\sigma_{static}\,a^3 \qquad \text{(Eq. K3[a])}$$

in which M_0 is seismic moment, $\Delta\sigma$ is static stress drop, and a is fault radius. Seismic moment is also related to moment magnitude (**M**) by (Hanks and Kanamori 1979 [DIRS 106061]):

$$M = \frac{2}{3}\log M_0 - 10.7 \qquad \text{(Eq. K4[a])}$$

Solving Equation K4[a] for M_0:

$$M_0 = 10^{1.5\,M+16.05} \qquad \text{(Eq. K5[a])}$$

Substituting Equation K5[a] on the left-hand side of Equation K3[a] and solving for static stress drop:

$$\Delta\sigma_{static} = \frac{7}{16}(10^{1.5M+16.05})\,a^{-3} \qquad \text{(Eq. K6[a])}$$

Thus, if the moment magnitude and fault radius for an earthquake are known, the static stress drop can be determined.

As part of the PSHA for Yucca Mountain, six seismic source characterization teams used available data to interpret, for fault sources, the probability of activity, fault geometry, and rate of future earthquakes as a function of magnitude (CRWMS M&O 1998 [DIRS 103731], Section 4, Appendix E). Fault geometry was characterized by fault length (L), fault dip (θ), and the vertical extent of faulting (h). Using fault dip and the vertical extent of faulting, down-dip fault width (W) can be calculated as:

$$W = h/\sin(\theta) \qquad \text{(Eq. K7[a])}$$

As part of the characterization of earthquake occurrence rate, a maximum moment magnitude ($\mathbf{M_{max}}$) was assessed for each source.

For both fault geometry and earthquake occurrence rate, epistemic uncertainty was also assessed by the PSHA expert teams. Uncertainty was represented using discrete probability distributions typically consisting of three to six values for a given parameter. For fault geometry, factors contributing to uncertainty included alternative interpretations of field geologic mapping, uncertainty in the configuration of faults at depth, alternate tectonic models with differing implications for the vertical extent of the seismogenic crust or the depth at which detachment surfaces existed, and limited data on the extent of a fault that had experienced rupture during the Quaternary Period. For $\mathbf{M_{max}}$, uncertainty derived primarily from alternative empirical relations between moment magnitude and fault characteristics such as rupture length, rupture area,

maximum displacement, and slip rate. Because the probability distribution for $\mathbf{M_{max}}$ is dependent on fault geometry, the distribution varies for a given source depending on the combination of fault rupture length, dip, and vertical extent of faulting being considered.

Fault source characterization data used in the PSHA are part of the data with DTN: MO0401MWDRPSHA.000 Rev 3 [DIRS 185267]. For each seismic source characterization expert team, "src_input" files contain the various combinations of $\mathbf{M_{max}}$, fault dip, vertical extent of faulting, fault occurrence rate, and logic tree branch probability for each fault source. Fault length data are implicitly contained in "src.GEOM" files that contain geographic coordinates defining a source. However, rather than compute length from the src.GEOM files, rupture length data are taken from CRWMS M&O (1998 [DIRS 103731], Appendix E) in which the length data are tabulated for each PSHA team. It is assumed that for an $\mathbf{M_{max}}$ earthquake, the entire potential rupture area is involved. This is consistent with the way in which fault geometry data were used in estimating $\mathbf{M_{max}}$ using empirical relations. Only characterization data for "local" faults, as identified by each PSHA team, were analyzed. One exception to this rule was the inclusion of data from the SDO team for the Bare Mountain fault, even though they considered that fault as "regional." All other teams considered the Bare Mountain fault as a "local" fault.

To calculate static stress drop based on PSHA fault source characterization data, fault rupture area for an $\boldsymbol{M_{max}}$ earthquake is taken as the fault rupture length times the down-dip width. The radius (a) of an equivalent circular source with the same rupture area is then computed as:

$$a = \sqrt{\frac{L \times W}{\pi}} \qquad \text{(Eq. K8[a])}$$

Static stress drop is then determined from Equation K6[a]. Static stress drop is calculated for each $\boldsymbol{M_{max}}$ in a given $\boldsymbol{M_{max}}$ uncertainty distribution for each interpreted combination of rupture length and down-dip width (rupture area) for each local fault source for each PSHA team resulting in 3150 estimates of static stress drop from the PSHA seismic source characterization.

This treatment of the fault source characterization data differs somewhat from its use in calculating ground motion hazard. For calculation of ground motion hazard, for a given $\boldsymbol{M}$, a fault rupture length is determined from the Wells and Coppersmith (1994 [DIRS 107201], Table 2A, RDL, All) regression relation between $\boldsymbol{M}$ and subsurface rupture length (L). This value for L is used unless it exceeds the maximum rupture length interpreted for the source, in which case the maximum rupture length value is used. Down-dip rupture width is taken as equal to rupture length (i.e., an aspect ratio of 1.0), unless that value exceeds the maximum down-dip rupture width, in which case the maximum down-dip rupture width is used. The rupture area corresponding to the given value of $\boldsymbol{M}$ is then stochastically located on the fault and used to compute the distance (R) between the fault and the reference site for ground motion hazard. The PSHA ground motion prediction equations are then used to calculate ground motion at the reference site for the given source geometry and $\boldsymbol{M}$. Thus, for a given $\boldsymbol{M_{max}}$, the rupture area used to determine (R) may be less than the maximum rupture area associated with $\boldsymbol{M_{max}}$ that is used to calculate static stress drop and bounding water table rise. However, for combinations leading to larger static stress drops (i.e., relatively high $\boldsymbol{M_{max}}$ and relatively small rupture area),

the ground motion calculations will tend to use the full interpreted rupture area, consistent with the static stress drop calculations.

To estimate the range of hydrologic response associated with the PSHA seismic source characterization, each static stress drop was taken with its associated vertical extent of faulting and used to calculate an earthquake-induced bounding water table rise using Equation K2[a]. Results are summarized in Table K-1[a] in terms of 25-m water-table-rise bins. Of the 3150 values, 13 are greater than 175 m. The nominal distance between the water table elevation, both current and for future, wetter climates, and the elevation of the lowest waste emplacement drift is 187 m. Thus, a small number of calculated values for bounding water table rise exceed the distance between the water table and the lowest emplacement drift.

Table K-1[a]. Summary of Bounding Water Table Rise Values Consistent with Seismic Source Characterization for the PSHA

Water Table Rise Bins (m)	Water Table Rise Value Counts						
	AAR	ASM	DFS	RYA	SBK	SDO	Combined
0 - 25	693	144	278	291	219	750	2,375
25 - 50	35	45	0	120	72	95	367
50 - 75	55	12	0	6	14	98	185
75 - 100	27	12	0	0	9	75	123
100 - 125	24	4	0	0	8	11	47
125 - 150	18	3	0	0	1	1	23
150 - 175	12	0	0	0	0	5	17
175 - 200	5	0	0	0	0	0	5
200 - 225	2	0	0	0	0	1	3
225 - 250	1	0	0	0	0	1	2
> 250	1	1	0	0	0	1	3
	873	221	278	417	323	1,038	3,150

NOTE: The columns under "Water Table Rise Value Counts" give the results for each of the six seismic source and fault displacement characterization teams that participated in the PSHA along with the combined results. The team acronyms correspond to the following teams: AAR=W.J. Arabasz, R.E. Anderson, A.R. Ramelli; ASM=J.P. Ake, D. B. Slemmons, J. McCalpin; DFS=D.I. Doser, C.J. Fridrich, F.H. Swan; RYA=A.M. Rogers, J.C. Yount, L.W. Anderson; SBK=K.D. Smith, R. Bruhn, P.L.K. Knuepfer; SDO=R.B. Smith, C. dePolo, D.W. O'Leary (CRWMS M&O 1998 [DIRS], Table ES-1)

Source: Appendix K[a], Electronic Supplement, file: *PSHA Static Stress Drops R1.xlsm*, worksheet: *Summary 1*.

The above results are independent of the interpreted probabilities a given fault source is active, and that, if active, a given source geometry and M_{max} represent the conditions at Yucca Mountain. The results are also independent of the rate of occurrence of an M_{max} event. Considering these probabilities and M_{max} occurrence rates for the 13 cases with a bounding water table rise greater than 175 m (including two cases with a bounding water table rise between 175 and 187 m), it is determined that for nine of those cases the annual combined probability of occurrence is significantly less than 10^{-8} (Table K-2[a]). For the remaining four cases, the occurrence probabilities are between about 10^{-6} and 10^{-8}. Taking into account the bounding

nature of the Kemeny and Cook model used to calculate water table rise, these results provide support for the conclusion that seismically induced water table rise exceeding the gap between the elevation of the static water table and the lowest waste emplacement drift (about 187 m) has a low probability and can be excluded from the TSPA model.

Table K-2[a]. Probabilities Associated with Source Characterization Cases Giving Bounding Water Table Rise Greater than 175 m

NOTES: 1. Branch probability is for the logic tree branch reflecting a given combination of source geometry, Mmax probability distribution, and occurrence rate determination approach.
2. Annual occurrence rate is for M_{max}. Different values reflect alternative interpretations of occurrence rate for the given source geometry.
3. M_{max} probability is the probability that M_{max} is represented by the value given.
4. Interpretation Probability: The SDO team interpreted that there is a 0.5 probability that the Stagecoach Road fault acts as an independent seismic source and not in combination with other faults.

K4.2[a] BOUNDING WATER TABLE RISE CONSISTENT WITH PROBABILISTIC FAULT DISPLACEMENT HAZARD RESULTS

A second approach to assessing seismically related water table rise in light of the PSHA combines the fault displacement hazard results with the fault source geometry characterizations. Kanamori and Anderson (1975 [DIRS 182963], Figure 1) summarize the relation between static stress drop ($\Delta\sigma$), average displacement across the fault rupture ($\overline{D}$), and fault dimension. For a circular fault:

$$\Delta\sigma_{static} = \frac{7\pi}{16}\mu\frac{\overline{D}}{a} \qquad \text{(Eq. K9[a])}$$

in which μ is shear modulus (taken as 3×10^{11} dyne-cm) and a is fault radius.

In the PSHA for Yucca Mountain, fault displacement hazard was determined for a suite of demonstration points covering the range of fault conditions expected to be encountered at the site (CRWMS M&O 1998 [DIRS 103731], Section 4.3.2). The hazard at sites on faults displaying evidence of activity during the Quaternary Period included contributions from both primary faulting and from secondary displacement associated with primary faulting on other active faults. Sites on pre-Quaternary faults, fractures with no displacement, and intact rock were assessed to be subject to hazard from only secondary displacements. Two of the demonstration sites were on block-bounding Quaternary faults: the Bow Ridge fault and the Solitario Canyon fault. Fault displacement hazard for the Solitario Canyon fault was the highest of all the demonstration sites. Extrapolation of the logarithms of displacement and probability of exceedance indicate that a fault displacement of about 1,300 cm has a mean annual probability of exceedance 10^{-8}. This value bounds fault displacement that need be considered in the TSPA (Assumption K5.2).

To evaluate the implications of the PSHA displacement hazard results, static stress drop was calculated using Equation K9[a] and an average fault displacement value of 1,300 cm. Fault radius was calculated using Equation K8[a] as described in Section K4.1[a]. The calculation was

carried out for PSHA fault source characterizations of the Solitario Canyon fault, the Paintbrush Canyon fault, or fault combinations including one or both of those faults. For each fault source, alternative fault geometries representing epistemic uncertainty were evaluated to give a range of bounding water table rise. A weighted average water table rise was calculated using the logic tree branch probabilities associated with the alternative interpretations of fault geometry. Results are summarized in Table K-3[a].

Table K-3[a]. Bounding Water Table Rise for an Earthquake Displacement with a 10^{-8} Mean Annual Probability of Being Exceeded

NOTES:
1. To compute the average water table rise, values are weighted according to their logic tree branch probabilities times the maximum magnitude probability and normalized to the total weight that the given interpretation is active.
2. Interpretation weight is the probability that a given fault configuration (i.e., acting independently, linked with other faults) represents the tectonic conditions at Yucca Mountain. The interpretation weight is the sum of the underlying logic tree branch probabilities when the fault configuration is active.

Calculated values of average weighted water table rise, based on a fault displacement of 1,300 cm and using the fault source characterization results from the PSHA expert teams, are 122 m or less. Thus, for a displacement with a nominal 10^{-8} mean annual probability of being exceeded, a bounding estimate of water table rise still leaves a distance of 65 m or more between the elevation of the water table and the elevation of the lowest waste emplacement drift (an approximately 187-m distance in the absence of seismically induced water table rise). Note also that for most fault interpretations evaluated, the logic tree branch probability is significantly less than 1. Consequently, exclusion of FEP 1.2.10.01.0A (Hydrologic Response to Seismic

Activity), from the TSPA is consistent with the seismic source characterization interpretations and the fault displacement hazard results of the PSHA.

K5[a]. CONCLUSIONS

FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity), describes some earthquake-related hydrologic effects, including seismically induced water table rise. The low elevation of the water table at Yucca Mountain is a key attribute of the site. Within the repository footprint, the present-day water table varies from around 730 m above mean sea level in the south to less than 850 m above mean sea level in the north (BSC 2004 [DIRS 169855], Figure 6-2). The repository elevation for emplacement drifts ranges between 1,037 m above mean sea level in the north (BSC 2007 [DIRS 179640], Table 14) and 1,105 m above mean sea level in the south (BSC 2007 [DIRS 179640], Table 12), indicating that the present-day water table depth below the repository horizon ranges from 187 m in the north, based on a repository elevation of 1,037 m and water table elevation of 850 m, to 375 m in the south, based on a repository elevation of 1,105 m and water table elevation of 730 m. For future, wetter climates, the elevation of the water table is taken to have a uniform value of 850 m. This appendix examines the potential for seismically induced water table rise to reduce the minimum 187-m distance between the elevation of the water table and the lowest elevation of a waste emplacement drift.

In a simple model, Kemeny and Cook (1990 [DIRS 129658], 1992 [DIRS 100989]) relate seismically induced water table rise to earthquake static stress drop and the vertical extent of faulting. The Kemeny and Cook model is developed to bound seismically induced water table rise.

Although, in general, static stress drop was not explicitly assessed during the PSHA for Yucca Mountain, characterizations of fault length, dip, vertical extent of faulting, and M_{max} carried out by the expert teams can be used to infer a static stress drop. Using these data as input to the Kemeny and Cook model demonstrates that, for 3139 out of 3150 cases, the calculated water table rise is less than the 187 m distance between the elevation of the water table and the lowest waste emplacement drift. This observation is independent of the probability that a given case represents the actual geologic conditions at Yucca Mountain. When seismic source characterization probabilities are taken into account along with the rate of occurrence of M_{max} events, it is determined that 7 of the 11 cases for which calculated water table rise exceeds 187 m have probabilities more than an order of magnitude less than 10^{-8}. Taking into account the intentional bounding nature of the Kemeny and Cook model, the results support exclusion of seismically induced water table rise from the TSPA.

Fault displacement hazard results from the PSHA also demonstrate that seismically induced water table rise can be excluded from the TSPA. For the fault sites and conditions evaluated in the PSHA, the Solitario Canyon fault has the greatest displacement hazard. For a mean annual probability of exceedance of 10^{-8}, the fault displacement hazard is about 1,300 cm. Using this value as the average displacement on the Solitario Canyon and Paintbrush Canyon faults, static stress drop can be calculated using the fault geometry data from the PSHA seismic source characterization. Cases for the Solitario Canyon and Paintbrush Canyon faults alone, and in combination with other faults, give a maximum bounding water table rise of 122 m. Thus,

calculated seismically induced water table rise using this approach maintains a gap of 65 m or more between the elevation of the water table and the lowest waste emplacement drift.

These analyses support exclusion of FEP 1.2.10.01.0A (Hydrologic Response to Seismic Activity), from the TSPA.
