1.0 Purpose

The purpose of this calculation is to determine the required minimum burnup as a function of initial pressurized water reactor (PWR) assembly enrichment that would permit loading of fuel into the 21 PWR waste package (WP), as provided for in QAP-2-0 Activity Evaluation, *Perform Criticality, Thermal, Structural, & Shielding Analyses* (Reference 7.1). The results are intended to show that PWR spent nuclear fuel (SNF) assemblies whose actual burnup exceeds the required minimum burnup may be loaded into a 21 PWR waste package with a stainless steel/boron criticality control basket design.

2.0 Method

The solution method employed was to use the SAS2H sequence of the SCALE 4.3 computer code system (Reference 7.4) to determine the isotopics of the SNF for various initial fuel enrichments and SNF burnups. The CRAFT computer code was used to control the processing of the eighteen axial nodes of the SNF burnup profile and simplify the usage of SAS2H. The isotopic description of the spent fuel provided by SAS2H was entered into a criticality model, and the Monte Carlo N-Particle Version 4A computer code (MCNP4A) (Reference 7.2) was used to calculate k_{eff} for criticality safety calculations.

3.0 Assumptions

3.1 The Crystal River Unit 3 SNF assembly A08 is representative of typical PWR SNF. This assumption is used in Section 5.1.

3.2 The isotopic contents created by adjusting the specific power are representative of isotopics which would be generated by typical irradiation cycles. This assumption is used in Section 5.5.

3.3 A modification to the Crystal River Unit 3 SNF assembly A08 to add a generic Burnable Poison Rod Assembly (BPRA) is representative of PWR SNF which has contained a BPRA during one or more irradiation cycles. This assumption is used in Section 5.3.

3.4 The bias of k_{eff} is 0.02 and the administrative limit is 0.95. This assumption is used in Sections 6.1 and 6.2.

4.0 Use of Computer Software

The calculation of nuclear reactivity of the fresh fuel configuration for the 21 PWR Uncanistered Fuel (UCF) WP was performed with the MCNP4A computer code. MCNP4A calculates k_{eff} for a variety of geometric configurations with neutron cross sections for elements and isotopes

described in the Evaluated Nuclear Data File version B-V (ENDF-B/V). MCNP4A is appropriate for the fuel geometries and materials required for these analyses. The calculations using the MCNP4A software were executed on a Hewlett-Packard workstation. The software qualification of the MCNP4A software, including problems related to calculation of k_{eff} for fissile systems, is summarized in the Monte Carlo N-Particle code Software Qualification Report for MCNP4A (Reference 7.3). The MCNP4A evaluations performed for this design are fully within the range of the validation for the MCNP4A software used. Access to and use of the MCNP4A software for this analysis was granted by Software Configuration Management and performed in accordance with the QAP-SI series procedures. Inputs for the MCNP4A software are included in Attachment II as described in the following design analysis.

The calculation of the isotopic contents of the PWR SNF assembly was performed with the SAS2H sequence of the SCALE 4.3 Modular Code System. SAS2H is designed for spent fuel depletion calculations to determine spent fuel isotopic content, decay heat rates, and radiation source terms. Thus, SAS2H is appropriate for the generation of isotopic contents for the calculations of this analysis. The calculations using the SAS2H software were executed on a Hewlett-Packard workstation. The software qualification of the SAS2H software, including benchmark problems related to generation of isotope contents, is summarized in the Software Qualification Report for the SCALE Modular Code system (Reference 7.5). The SAS2H evaluations performed for this design are fully within the range of the validation for the SAS2H software used. The associated 44GROUP cross section library was used for these calculations. Access to and use of the SAS2H software for this analysis was granted by Software Configuration Management and performed in accordance with the QAP-SI series procedures. Inputs for the CRAFT software are included in Attachment II as described in the following design analysis.

The isotopic contents of spent PWR fuel for long time periods were calculated with the ORIGEN-S module which is a part of the SAS2H code sequence. The SAS2H sequence provides isotopic data at the time of discharge from the reactor and for 5, 10, 15, 20, and 25 years after discharge. ORIGEN-S is run as a stand-alone module to provide isotopic data at longer time periods using the decay constants contained within the 44GROUP cross section library, to facilitate future analyses in the repository environment.

The CRAFT computer code (Reference 7.6) was used to orchestrate the performance of SAS2H runs for the eighteen axial nodes of the SNF assembly. The CRAFT computer code was developed by Waste Package Operations to facilitate isotopic calculations for burnup credit evaluations, and is thus used within its range of validity.

4.1 Software Approved for QA Work

4.1.1 MCNP 4A HP 9000 Version, CSCI: 30006 V 4A, installed on a Hewlett Packard Apollo 9000 Series Workstation.

The input files used are echoed in the output files. The output files are provided on CD-ROM recordable laser disc as Attachment II.

a) The MCNP 4A computer code (Reference 7.3) is an appropriate tool to be utilized to determine the criticality potential, k_{eff}, of fresh and spent lattices of PWR fuel assemblies.
b) This software has been validated over the range within which it was used.
c) It was previously obtained from the Software Control Management (SCM) in accordance with appropriate procedures.

4.1.2 SCALE 4.3 HP 9000 Version, CSCI: 30011 V4.3, installed on a Hewlett Packard Apollo 9000 Series Workstation.

The input files used are echoed in the output files. The output files are provided on CD-ROM recordable laser disc as Attachment II.

a) The SCALE 4.3 computer code (Reference 7.4) is an appropriate tool to be utilized to perform isotopic depletion calculations of PWR fuel assemblies via the SAS2H and ORIGEN-S modules.
b) This software has been validated over the range it was used.
c) It was previously obtained in accordance with appropriate procedures.

4.2 Software Routines

4.2.1 CRAFT – A Commercial Reactor Assembly Follow Taskmaster
Identification: CRAFT Version 1.0, compiled on December 16, 1996

Description and Testing: The CRAFT software routine (Reference 7.6) was written to automate the production of SAS2H input decks as required to support fuel assembly depletion calculations relevant to CRC evaluations. All calculations performed by the CRAFT code were verified by visual inspection and/or hand calculations. The CRAFT code, Version 1.0, compiled on December 16, 1996, was utilized to orchestrate the fuel assembly depletion calculations included in this analysis. CRAFT prepares the input files for SAS2H, runs SAS2H, and scans the SAS2H output file to remove unused text at the beginning of the SAS2H output file and produce a .CUT file. The .CUT file contains the isotopic data.

4.2.2 The UNIX operating system of the Hewlett-Packard computer was used to collect the data for the eighteen axial nodes from the CRAFT .CUT files and store the simplified output into a .SUM file for further processing. The UNIX awk command was then used to compare the isotopic name of each data line to a list of the principal isotopes, and include only isotopes on the principal isotope list in the .RES file which it produces. The

.RES file contains isotopic data for discharge, five years, ten years, fifteen years, twenty years, and twentyfive years cool time. The loading curves were calculated using only the spent fuel isotopics with a five year cool time but data for the other cool times was preserved. Eu-155 was included in the .RES files to facilitate future evaluation of the behavior of isotopics at long time periods, since Eu-155 is a parent nuclide in a decay chain for a principal isotope.

4.2.3 EXCEL - Microsoft® Excel 97 is a commercially available program which was used to convert the format of the isotopic data from grams to atoms per barn-cm. The converted data was inserted into an input file for later use by the MCNP4A program. The oxygen content of the spent fuel was also computed by Excel by summing the masses of the uranium isotopes and applying the ratio of atomic masses of oxygen and uranium in UO_2 (32/238).

5.0 Calculation

The calculation of loading curves is described in the Actinide-Only Burnup Credit Topical Report (Reference 7.7), Chapter 4, which describes the process of evaluation of the loading curve. The calculation is performed for PWR assemblies both with and without BPRAs inserted.

5.1 Method

The method of calculation is based upon the calculation of the isotopic constituents of irradiated fuel using the SAS2H sequence of the SCALE computer code system. The SAS2H sequence provides the isotopics present in the spent fuel when it is discharged from the reactor, and at later times after discharge. A period of five years after discharge is used for these calculations. The A08 assembly from Crystal River Unit 3 is used as the basic model for the PWR fuel assembly (Reference 7.6). The isotopic content for this assembly is calculated with initial U-235 enrichments ranging from 2.5 weight percent through 6.0 weight percent and with discharge burnups ranging from 10 GWd/MTU through 60 GWd/MTU. The specific power of the assembly is adjusted up or down to provide the desired discharge burnup. In actual plant operation, a longer or shorter cycle would typically be used which would result in a range of possible burnups for a given initial enrichment. In such cases, the isotopics are dependent upon the cycle lengths, which affect the amount of cool time available for isotopes to decay. The use of an adjustable specific power with a fixed irradiation cycle avoids the introduction of variability due to changing cycle times.

5.2 Use of Loading Curves

A burnup credit loading curve depicts the relationship between the initial enrichment of a fuel assembly and the required minium burnup needed to suppress the reactivity of that fuel assembly sufficiently to allow it to be safely loaded into the waste package. Any assembly whose burnup

exceeds the required minimum burnup, given the initial enrichment of the fuel assembly, may be placed in the waste package. The area in the figure above the loading curve line is the region of acceptable fuel assemblies, while assemblies whose enrichment and burnup place them into the area below the loading curve line may not be loaded.

The operator who is loading a waste package must be provided with a table of fuel assembly identifiers, initial enrichments, and burnups, and also whether the assembly contained a BPRA. The operator would verify that a given assembly falls into the acceptable region of the loading curve based upon this information.

5.3 Use of CRAFT ~~Computer Code~~ Software Routine[10/20/98, A.H.W] for Isotopic Generation by SAS2H

The CRAFT ~~computer code~~ software routine[10/20/98, A.H.W] automates the process of calculating the principal isotopes present in spent fuel five years after it has been discharged from the nuclear reactor. CRAFT orchestrates the use of the SAS2H isotopic depletion code system so that the detailed burnup history for each axial node of the assembly is properly represented in SAS2H. Since SAS2H can only model a single fuel assembly configuration, including presence of control rods, burnable absorbers, and variable axial profiles, the CRAFT code separates information describing these aspects of the fuel burnup into individual SAS2H runs. The PWR assemblies were modeled with an 18 axial-node model, using actual PWR data from Crystal River Unit 3 for assembly A08 (Reference 7.6). The A08 assembly did not contain BPRAs at any point during its irradiation, so a generic BPRA with a boron loading typical of the Crystal River cores was created, with 2.1 wt% B_4C. The CRAFT code was then used to produce isotopic data for a range of initial enrichments and burnups that encompasses the typical ranges found in commercial PWR fuel. The selected range spans first cores, which have low initial enrichments and burnups, and reaches to a high initial enrichment of 6.0 wt% and a burnup of 60 GWd/MTU.

5.4 CRAFT Input Models

The CRAFT input decks used in this analysis are listed in Attachment I; an example deck for assembly A08 with an initial enrichment of 4.0 wt% and a burnup of 35 GWd/MTU is listed in Figure 5.4-1. CRAFT inputs at different enrichments and cycle average burnups were created by varying this input to adjust the nodal burnups.

5.5 Modeling of Irradiation History

The operation of commercial reactors is such that higher initial fuel enrichments are required to reach higher burnups, and higher burnups are desirable in that the length of the operating cycle is longer and the longer cycles provide better utilization of the power plant. The longer a reactor can run before it is shut down for refueling, the more economical it becomes even though the fuel, which is more enriched, is somewhat more expensive. Thus it would be expected that the irradiation cycle length would be dependent upon the initial enrichment. The CRAFT input decks do not reflect this actual fuel behavior; instead the cycle time periods were fixed for all calculations and the specific power of the fuel assembly was varied. This approach provides a common time basis for all isotopic data produced by SAS2H and avoids discontinuities which could appear between data points where, in actual practice, a fuel assembly would achieve lower burnup than the standard design value if it were prematurely removed from the reactor core, and could only achieve a higher burnup than the design value if it were overburned by replacing it into the reactor core for one more cycle than normal. Thus the actual history of an assembly which is burned less or more than the average (for its type and initial enrichment) would be unpredictable, since it would be based upon specific plant experiences, such as damaged assemblies which might be removed early and be replaced by assemblies which had been previously burned to approximately the design value. This unpredictable nature of actual irradiation histories is the reason for restricting the loading curve analyses to a single irradiation history, with an adjustable specific power to attain the desired burnup.

The scaling of specific power to provide a desired total burnup is accomplished by use of equation 5.5-1.

Equation 5.5-1.

$$P(i,j) = P(i,A08) * [B(j)/B(A08)]$$, where:

P(i,j) is the specific power for the ith axial node (nodes 1-18) and the jth burnup step. (There are three irradiation cycles with a total of six statepoints or burnup steps.)

P(i,A08) is the specific power for the ith axial node for Crystal River Unit 3 assembly A08.

B(j) is the burnup for the jth burnup step. The sum over j of all values of B(j) is the total burnup for the assembly.

B(A08) is the actual (total) burnup for assembly A08.

The values for each node and each statepoint are entered into a CRAFT input file (as shown in Figure 5.4-1) as the final set of six groups of data consisting of the node heights and the associated specific powers. The beginning of this set is indicated in Figure 5.4-1 with a marker phrase "(*** Specific Power Data Adjusted for Desired Burnup Begins Here***)". The initial

enrichment desired is also entered in the CRAFT input file as the fifth data entry at the beginning of the file.

5.6 MCNP4A Criticality Models

The MCNP4A model of the waste package was broken into eighteen axial segments to mimic the eighteen nodes analyzed by CRAFT and SAS2H. Fuel assembly end fittings and reflector regions above and below the fuel ends were included, as well as a detailed model of the waste package fuel basket and the waste package shells and ends. The cross section of the fuel basket shown in Figure 5.6-1 illustrates the arrangement of the 21 PWR fuel assemblies in the basket structure, surrounded by the waste package walls. Each fuel assembly is contained within a square ferritic steel tube inserted within a stainless steel/boron eggcrate fuel basket. Aluminum heat transfer shunts are inserted between the ferritic steel tube and stainless steel/boron eggcrate structure, as illustrated in Figure 5.6-2. The fuel assemblies rest against the eggcrate structure because the Waste Package rests in a horizontal position in the repository. These arrangements are documented in the 21-PWR Waste Package Disposal Container Assembly drawing series (Reference 7.8). The waste package was treated as flooded with pure water at one gram per cubic centimeter density, to provide the most conservative reactivity results. The nominal expected boron content was used in the stainless steel/boron alloy of the spent fuel basket. An example MCNP4A model input is given in Figure 5.6-4. The isotopic contents calculated by SAS2H, under the direction of CRAFT, were inserted into the MCNP4A model in the fuel cell card images for each enrichment/burnup data point which was analyzed. If an assembly contained a BPRA during its irradiation, its isotopic contents are more reactive than an assembly which did not. All assemblies are modeled without BPRAs in the guide tubes for the criticality analyses since no criticality credit is given for the BPRAs, even if they were to be present. The fuel assembly modeled in the MCNP4A analyses is a generic design and is not identical to assembly A08. The specific values of important model parameters are given in Table 5.6-1. Material densities are obtained from Reference 7.9.

Table 5.6-1. MCNP4A Model Parameters

Model Parameter	Value
Inner Dimension of Ferritic Steel Square Tube	226 mm (nominal 9 inches)
Thickness of Ferritic Steel Tube Wall	5 mm, $\rho = 7.832$ g/cm^3
Thickness of Aluminum Thermal Shunt	5 mm, $\rho = 2.700$ g/cm^3
Boron Content of Stainless Steel/Boron Eggcrate	1.6 weight percent in ASTM SS316B6A, $\rho =$ 7.770 g/cm^3

Table 5.6-1. MCNP4A Model Parameters	
Model Parameter	Value
Thickness of Stainless Steel/Boron Eggcrate Plates	7 mm
Areal Density of Stainless Steel/Boron Plates	16 mg/cm^3 B-10

5.7 Isotopic Data at Long Time Periods

The decay of isotopes out to one million years was run as a stand-alone ORIGEN-S case after the SAS2H burnup calculation. The ORIGEN-S calculation uses the isotopic output from SAS2H and applies the decay constants contained within the 44GROUP cross section library to calculate the isotopic data at desired time periods. The isotopic data provided by these calculations are provided to facilitate future analyses in the repository environment, and are not used for the loading curves.

6.0 Results

The loading curves for the 21 PWR Waste Package are shown in Figure 6-1, and are tabulated in Table 6-1. Two curves are shown: one for PWR assemblies which contained a BPRA at some point in their irradiation (legend: BPRAs) and one for PWR assemblies which never contained a BPRA (legend: No BPRAs).

Figure 6-1. Loading Curve for a 21 PWR Waste Package for Uncanistered Spent Fuel

6.1 Fresh Fuel

The maximum enrichment of fresh, unirradiated fuel which can be loaded into the waste package sets the point at which no burnup is required. Fuel enrichments greater than this value require burnup credit. The determination of the maximum fresh fuel enrichment limit for the 21 PWR basket is made by calculating k_{eff} for a range of initial enrichments, and plotting these results against the initial enrichment. The resulting curve shows the dependence of waste package fuel basket reactivity versus initial fuel enrichment, as illustrated in Figure 6.1-1. The intersection of this curve and a line representing the desired k_{eff} value (the administrative limit, such as 0.95) occurs at the maximum fresh fuel enrichment limit. The k_{eff} plotted in this analysis include a margin of 0.02 for bias and uncertainty of the bias, plus a two sigma allowance for calculational uncertainty. The k_{eff} values calculated for the waste package with fresh fuel are tabulated in Table 6.1-1. Note that these fresh fuel assemblies do not contain BPRAs.

Figure 6.1-1. 21 PWR UCF Waste Package Maximum Fresh Fuel Enrichment Limit

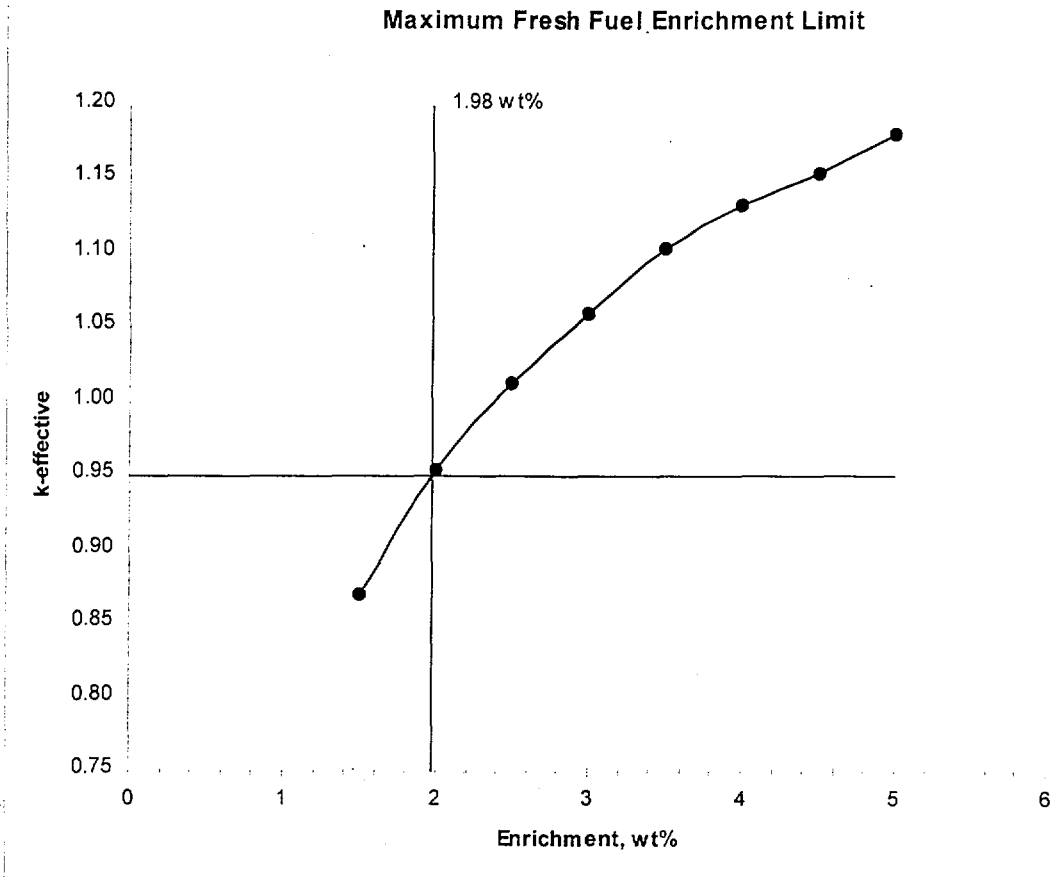

Table 6.1-1. 21 PWR UCF Waste Package Maximum Fresh Fuel Enrichment Limit

Principal Isotope Burnup Credit with Eighteen Axial Nodes			No BPRAs

UCF008	5.0 wt%	1.15748	0.00184	1.181

6.2 Burned Fuel

The required minimum burnup for each initial enrichment data point is determined by plotting the calculated k_{eff} versus the burnup, as shown in Figures 6.2-1 through 6.2-8. The k_{eff} plotted in this analysis include a margin of 0.02 for bias and uncertainty of the bias, plus a two sigma allowance for calculational uncertainty. The burnup value of the intersection of the plotted curve with the administrative limit for k-effective (0.95) is the required minimum burnup. Any burnup greater than this value will result in a k-effective less than 0.95. The required minimum burnup curves are plotted for enrichments of 2.5, 3.0, 3.5, 4.0, 4.5, 5.0, 5.5, and 6.0 weight percent U-235, with and without BPRAs. As suggested in the *Topical Report on Actinide-Only Burnup Credit for PWR Spent Nuclear Fuel Packages* (Reference 7.7), five or more k_{eff} calculations were performed for each curve.

6.2.4 4.0 wt% Initial Enrichment

The full range of burnups, from 10 through 60 GWd/MTU, was investigated at 4.0 wt% initial enrichment without BPRAs to determine if there were any interesting features in the curve; there were none, and the curve is continuous and does not change slope discontinuously. Thus it is an adequate procedure to calculate k_{eff} at five data points in the region where the curve crosses the limit for k_{eff} (0.95).

8.0 Attachments

Attachment I lists CRAFT computer input files, and output files (from SAS2H as run by CRAFT, and from MCNP4A). MCNP4A input files are echoed in the output files and are therefore not included separately. The files are saved on a CD-ROM as Attachment II. The CD-ROM was produced with a Hewlett-Packard 7200i CD-Rewritable drive using CD-Recordable media.

Attachment I: CRAFT Input Files and CRAFT and MCNP4A Output Files

Attachment I consists of CRAFT computer input files, consolidated SAS2H output files as run by CRAFT, and MCNP4A output files. The MCNP4A input files are echoed in the output files and are therefore not included separately in this attachment. The files are contained on an attachment CD-ROM of this calculation file (Attachment II). The information contained in this attachment is a listing of the various files that are contained on the attachment CD-ROM. An extraneous file with the filename A25.LST is contained on the CD-ROM with a file size of 262 bytes. This file is meaningless to this calculation and should be ignored.
